Sulphur may be united with tin by fusion; and forms with it a brittle mass, more difficultly fusible than pure tin. Sulphur has, in this respect, the same effect upon tin as upon lead. The alloy of tin lessens the fusibility of these very fusible metals; while it increases the fusibility of other difficultly fusible metals, as iron and copper.

§ 7. MERCURY OR QUICKSILVER.

MERCURY is a fluid metallic substance, of a bright silver colour, resembling lead or tin when melted; entirely void of taste and smell; extremely divisible; and congealable only in a degree of cold very difficultly produced, in this country, by art (see COLD and CONGELATION). It is the most ponderous of all fluids, and of all known bodies, gold and platina excepted; its specific gravity being to that of water nearly as 14 to 1. It is found to be specifically heavier in winter than in summer by 25 grains in 11 ounces.

Neither air nor water, nor the united action of these two, seem to make any impression upon mercury: nor is it more susceptible of rust than the perfect metals. Its surface, nevertheless, is more quickly tarnished than gold or silver; because the dust which floats in the air, quickly seizes on its surface. The watery vapours also, which float in the air, seem to be attracted by mercury.

From these extraneous matters, which only slightly adhere to it, mercury may be easily cleansed by passing it through a clean new cloth, and afterwards heating it: but if mixed with any other metal, no separation can be effected without distillation. In this process, a small portion of some of the metals generally arises along with the mercury. Thus, quicksil-

by Boyle.

ver distilled from lead, bismuth, or tin, appears less bright than before; stains paper black; sometimes exhibits a skin upon the surface; and does not run freely, or into round globules. Mr Boyle relates, that he has observed the weight of mercury sensibly increased by distillation from lead, and this when even a very moderate fire was made use of. By amalgamation with stellated regulus of antimony, and then being distilled after a few hours digestion, mercury is said to become, by a few repetitions of the process, more ponderous, and more active. The animated, or philosophic mercuries of some of the alchemists, are supposed to have been mercury thus prepared. By the same, or similar processes, seem to have been obtained the curious mercuries which Boyle declared he was possessed of, and made himself; which were "considerably heavier in specie than common quicksilver,—dissolved gold more readily,—grew hot with gold, so as to be offensive to the hand, and elevated gold in distillation." When quicksilver is to be distilled, it is proper to mingle it with a quantity of iron-filings; which have the property of making it much brighter than it can be otherwise obtained, probably by furnishing phlogiston.

1228
Mercurius
precipita-
tus per se.

By digestion in a strong heat for several months, mercury undergoes a considerable alteration, changing into a powder, at first ash-coloured, afterwards yellow, at length of a bright red colour, and an acrid taste; and is then called *mercurius precipitatus per se*. In this last state it proves similar to the red precipitate, prepared from a solution of mercury in nitrous acid. This calx proves less volatile in the fire than the mercury in its fluid state. It supports for some time even a degree of red heat. In the focus of a burning mirror, it is said to melt into glass when laid upon a piece of charcoal, and to revive into running mercury before it exhales. Evaporated by common fire, it leaves a small portion of a light brown powder; which, Boerhaave relates, bore a blast-heat; swelled into a spongy mass; formed with borax a vitreous friable substance; but vanished in cupellation. By a long continued digestion in a gentle heat, mercury suffers little change. Boerhaave digested it in low degrees of heat, both in open and close vessels, for 15 years together, without obtaining any other reward for his labour than a small quantity of black powder; which, by trituration, was quickly revived into running mercury. Constant triture, or agitation, produce a change similar to this in a short time. Both the black and red powders, by bare exposure to a fire sufficient to elevate them, return into fluid mercury. The red powder has been revived by simply grinding it in a glass mortar.

stillation.

1231
Explosion
by the va-
pours of
mercury.

In like manner, quicksilver remains unchanged by distillation. Boerhaave had the patience to distil 18 ounces of mercury upwards of 500 times over, without observing any other change than that its fluidity and specific gravity were a little increased, and that some grains of a fixed matter remained. The vapours of mercury, like those of all other volatile bodies, cause violent explosions if confined. Mr Hellot gives an account of his being present at an experiment of this kind: a person pretending to fix mercury, had inclosed it in an iron box closely welded. When the

mercury was heated, it burst the box, and dissipated in invisible vapours.

Mercury dissolves or unites with all metallic bodies, except three, viz. iron, arsenic, and nickel: in some cases it will absorb metals, particularly gold and silver, from their solutions in acids or alkalies; but does not act upon any metal when combined with sulphur, nor on precipitates made by alkalies, nor on calces by fire. Whatever metal it is united with, it constantly preserves its own white colour. It unites with any proportion of those metallic substances with which it is capable of being combined; forming, with different quantities, amalgams of different degrees of consistence. From the fluid ones, greatest part of the quicksilver may be separated by colature. Bismuth is so far attenuated by mercury, as to pass through leather with it in considerable quantity. It also promotes the action of quicksilver upon lead to a great degree; so that mercury united with $\frac{1}{4}$, $\frac{1}{8}$, or $\frac{1}{12}$ its weight of bismuth, dissolves masses of lead in a gentle warmth, without the agitation, triture, comminution, or melting heat necessary to unite pure mercury with lead. From these properties, this solution of bismuth in mercury becomes a proper solvent for pieces of lead lodged in the human body.

On triturating or digesting amalgams for a length of time, a blackish or dusky-coloured powder arises to the surface, and may be readily washed off by water. Some of the chemists have imagined, that the amalgamated metal was here reduced to its constituent parts: but pure mercury is by itself reducible to a powder of the same kind; and the metallic particles in this process, united with the mercury, are found to be no other than the metal in its entire substance. Some metals separate more difficultly than others; gold and silver the most so. Boerhaave relates, that if the powder which separates from an amalgam of lead be committed to distillation with vinegar in a tall vessel, the mercury will rise before the vinegar boils; that, by a like artifice, quicksilver may be made to distil in a less degree of heat than that of the human body: but Dr Lewis, though he made many trials, was never able to succeed.

By amalgamation with gold, mercury may become exceedingly fixed; so as not to be dissipable by the greatest heat. Concerning this, Dr Brandt relates the following curious experiment: "Having amalgamated fine gold with a large proportion of quicksilver, and strained off the superfluous mercury, he digested the amalgam in a close stopped vessel for two months with such a degree of heat, that a part of the quicksilver sublimed into the neck of the glass. The matter being then ground with twice its weight of sulphur, and urged with a gradual fire in a crucible, a spongy calx remained; which being melted with borax, and afterwards kept in fusion by itself for half an hour, in a very violent fire, still retained so much of the quicksilver as to become brittle under the hammer, and appear internally of a leaden colour. The metal being again amalgamated with fresh mercury, the amalgam again ground with sulphur, and exposed to an intense fire, a spongy calx remained as before. This calx being digested in two or three fresh parcels of aqua regia, a small portion of whitish matter remain-

ed at last undissolved. The paper which covered the cylindrical glass wherein the digestion was performed, contracted, from the vapours, a deep-green circular spot in the middle, with a smaller one at the side; whereas the aqua regia digested in the same manner by itself, or with gold, or with mercury, gave no stain. The first solution, on the addition of oil of tartar *per deliquium*, grew red as blood; on standing, it deposited, first, a little yellow calx, like aurum fulminans; afterwards, a bright matter like fine gold; and at last, a paler precipitate, inclining to green; its own deep red colour and transparency remaining unchanged. Being now committed to distillation, a colourless liquor arose; and the residuum, perfectly exsiccated, yielded, on edulcoration, a yellow calx of gold; which the alkaline lixivium had been unable to precipitate. The second solution turned green on the admixture of the alkaline liquor, and let fall a white precipitate, which turned black and brown. The several precipitates were calcined with twice their weight of sulphur, and then melted with four times their quantity of flint, and twelve of pot-ash, in a fire vehemently excited by bellows. The scoria appeared of a golden colour, which, on pulverization and edulcoration, vanished. At the bottom was a regulus, which looked bright like the purest gold; but was not perfectly malleable. Broken, it appeared internally white; and the white part amounted to at least one-third its bulk. Besides this lump of metal, there were several others, white like silver, and soft as lead."

1235
Supposed to
be convert-
ible into
water.

In Wilson's chemistry, we have a process for converting quicksilver into water, by dropping it by little and little into a tall iron vessel, heated almost to a white heat in the bottom. Over the mouth of this vessel were luted seven aludels; and on the top, a glass alembic head, with a beak, to which was fitted a receiver. The mercury was put in so slowly, that it required 16 hours for one pound. Every time that a little quantity of mercury was put in, it made a great noise, filling the aludel's head and receiver with white fumes. When the vessels were cooled, a little water was found in each of the receivers, and in the first and second some grains of crude mercury. The whole quantity amounted to 13 ounces and 6 drachms; which was expected to prove a powerful solvent of gold and silver: but, on trial, was found to be in no respect different from common water. On this experiment Dr Lewis has the following note.

1236
Dr Lewis's
detection
of the false-
hood of this
process.

"The possibility of converting mercury into water, or at least of obtaining a great quantity of water from mercury, has not only been believed by several great men in the chemical art, but some have even ventured to assert that they have actually made this change. Yet, nevertheless, they have delivered the history of this affair with such marks, as seem to make the reality of the change extremely doubtful. Mr Boyle (in his tract of *the producibleness of Chemical Principles*, annexed to *Scept. Chemist.* p. 235.) says, "that he once obtained water from mercury without additament, without being able to make the like experiment succeed afterwards." M. Le Febvre, who is generally looked upon as an honest practitioner, directs a process similar to that above (Wilson's), for obtaining of this mercurial water. But it is to be suspected, as Mr Hales very well observes (in his *Sta-*

tical Experiments, p. 200.), that Mr Boyle and others were deceived by some unheeded circumstance, when they thought they obtained a water from mercury, which should seem rather to have arisen from the lute and earthen vessels made use of in the distillation: for Mr Hales could not find the least sign of any moisture upon distilling mercury in a retort made of an iron gun-barrel, with an intense degree of heat; although he frequently cohobated the mercury which came over into the recipient. "In a course of chemical experiments, I repeated Mr Hales's process, and urged the mercury, which was let fall by little and little, through an aperture made in the gun-barrel, with a most intense degree of heat, without obtaining any water; but it being suspected by a bystander, that the mercury in this experiment came over before it had been sufficiently acted upon by the fire, by reason of the lowness of the neck of the distilling instrument, the experiment was varied in the following manner. Sixteen ounces of mercury were heated in a crucible, in order to evaporate any moisture that might have been accidentally mixed with it; and an iron gun-barrel of four feet in length, being placed perpendicularly in a good furnace, and a glass-head and recipient fitted to its upper part, the mercury was let fall by little and little into the barrel, and the fire urged with bellows. After each injection, the mercury made a considerable noise and ebullition, and arose into the head; where it soon condensed and trickled down, in the common form of running mercury, into the recipient, without the least perceptible appearance of any aqueous humidity."

Mercury is difficultly amalgamated with regulus of antimony and copper; for which some particular manœuvres are required. Two of Dr Lewis's receipts for uniting quicksilver with copper, we have already given (n° 1153.): with regulus of antimony, mercury, he says, may be perfectly united, by pouring a small stream of melted regulus into a considerable portion of mercury, made almost boiling hot. Another method directed by Henckel, is to put mercury into an iron mortar along with some water, and set the whole over the fire. When the water boils, a third or fourth part of melted regulus is to be poured in, and the mass ground with a pestle, till the amalgam is completed. The use of the water, as Dr Lewis observes, is to hinder the mercury from flying off by the heat of the regulus: but as the two are by this means not put together in so hot a state, the union is more difficult, and less perfect. The loss of the mercury, in the first process, may be prevented by using a large vessel, and covering it with a perforated iron-plate, through the hole in which the regulus is to be poured. This method is likewise applicable to the amalgamation of copper.

With sulphur, mercury unites very readily, forming by trituration, or simple fusion, a black powder or mass, called *Ethiops mineral*; which, by careful sublimation, becomes the beautiful red pigment called *vermillion*. (See SULPHUR, sect. iv.).

The extensive use of mercurius dulcis in medicine has rendered it an object to chemists to find out some method of preparing it with less expence and trouble, and with more certainty of its effects, than it can be by the methods hitherto mentioned. This is now accom-
plished

Mercury
or Quick-
silver.

plished through the industry of Mr Scheele, to whom chemistry in general has been so much obliged. His method is as follows :

“ Take half a pound of quicksilver, and as much pure common aquafortis. Pour it into a small cucurbit with a pretty long neck, stop the mouth with a little paper, and put it into warm sand. Some hours afterwards, when the acid appears no longer to act upon the quicksilver, the fire is to be augmented so as to make the solution nearly boil. This heat is to be continued for three or four hours, and the vessel now and then to be shaken. Towards the end, regulate the heat in such a manner that the solution shall gently boil for a quarter of an hour. In the mean time, dissolve $4\frac{1}{2}$ ounces of pure common salt in six or eight pounds of water ; pour this solution, still boiling, into a glass vessel, and immediately afterwards mix with it the above-mentioned solution of quicksilver, which also must be boiling, in small quantities at a time, with constant agitation. When the precipitate has settled, decant off the clear liquor, and pour hot water again on the precipitate, with which it is to be edulcorated, till the water standing upon it shall be entirely tasteless. Put the whole obtained by these means together, filter and dry it in a mild heat.”

1239
How to
obtain a
perfectly
saturated
solution of
quicksilver.

On this process it is remarked, that when the quicksilver no longer effervesces with the acid, one would imagine that a saturation had taken place. But this is far from being the case. By increasing the heat the solution is still able to dissolve a great quantity ; with this difference, however, that, whereas the quicksilver in the beginning is calcined, a great deal of it afterwards, in a metallic form, is dissolved, as appears from this, that not only no more elastic vapours ascend ; but also, that with fixed and volatile caustic alkalies a black precipitate is obtained ; otherwise, when the solution contains only calcined quicksilver, the precipitate is yellow. If the black precipitate be gently distilled, quicksilver arises, and there remains a yellow powder, which is that part of the metal that was calcined by the nitrous acid. The fire must at any rate be augmented, in order to keep the mercurial calx dissolved, the compound of this metal and nitrous acid being extremely apt to crystallize even in the heat. There commonly remains some undissolved quicksilver ; but it is always better to take too much than too little ; for the more metal the mercurial solution contains, the more mercurius dulcis is obtained at last. The quantity here mentioned usually produces $8\frac{1}{2}$ ounces of mercurius dulcis. The mercurial solution must be cautiously poured into that of sea-salt, that no mercury may follow. Two ounces of salt would be sufficient for the precipitation of all the quicksilver ; but when so small a quantity is used, it may easily happen, that some superabundant corrosive sublimate may adhere to the precipitate, which water alone is incapable of entirely separating. Among other advantages this method of making mercurius dulcis possesses, it is none of the least, that the powder is much finer than any to which it can be reduced in the common way by trituration, however long continued.

§ 8. ZINC.

This is a semimetal of a bluish white colour. It is

the least brittle of any of the semimetals ; and when amply supplied with phlogiston, which may be done by treating it in close vessels with inflammable matters, it possesses a semiductility, by which it may be flattened into thin plates. When broken, it appears formed of many flat shining plates or facets, which are larger when slowly than when hastily cooled. When heated, it is very brittle ; and crackles like tin, only louder, when bent. Exposed to the air, it contracts in length of time a yellowish rust. Its specific gravity, according to Dr Lewis, is to that of water as $7\frac{1}{10}$ to 1. It begins to melt as soon as red-hot ; but does not flow thin till the fire is raised to a white heat. Then the zinc immediately begins to burn with an exceedingly bright and beautiful flame. Kept just in fusion, it calcines slowly ; not only on the upper surface, but likewise round the sides, and at the bottom of the crucible. If several pieces are just melted together, the mass, when grown cold, may be broken into the same number ; their union being prevented by a yellowish calx, with which each piece is covered over. M. Malouin relates, in the French Memoirs for 1742, that a quantity of zinc being melted six times, and the fusion continued fifteen hours each time, it proved, on every repetition, harder, more brittle, less fusible, and less calcinable : that after the two first fusions, its colour was grey ; after the third, brown ; and after the fourth, black : that the fifth rendered it of a slate-blue ; and the sixth of a clear violet.

1240
Deflagra-
tion.

So violent is the deflagration of zinc, that the whole of its calx is sublimed by it, in the form of light flocks, or wool ; which, however, are easily reduced to a fine powder. These are used in medicine, and reckoned an excellent remedy in epileptic cases. When once sublimed, they are by no means capable of being elevated again by the most violent heat. In a heat far greater than that in which they first arose, they suffer no alteration ; in a very vehement one, they melt, according to Henckel, into a semiopaque green glass. Vitrified with borax, they give a grey, or brownish, glass. From the brightness of the flame of burning zinc, and the garlic smell which it is said to emit, some have concluded that zinc contained the phosphoric acid ; which, from some other circumstances, is not altogether improbable.

1241

Flowers of
zinc.

The flowers of zinc have been thought very difficultly, or not at all, reducible to their metallic form by an addition of phlogiston. But Dr Lewis observes, that this difficulty proceeds not from their unfitness to be restored into the form of zinc, but from the volatility of the semimetal, which occasions its being dissipated in fumes, if the common methods are made use of. All calces, those of iron excepted, require a greater heat for their fusion than that in which the metal itself melts ; and as a full melting heat is the greatest that zinc can sustain, it burns and calcines the instant of its revival, if the air is admitted ; and in close vessels escapes, in part at least, through their pores. On mixing flowers of zinc with powdered charcoal, and urging them with a strong fire in a crucible, a deflagration and fresh sublimation ensue : sufficient marks that the zinc has been reduced to its metallic form ; for as long as it remains in the state of calx, neither of these effects can happen. If the vessel is so con-

1242
Dr Lewis's
method of
reducing
them.

trived!

Zinc. trived as to exclude the air, and at the same time to allow the reviving semimetal to run off from the vehemence of the heat, into a receiver kept cool, the zinc will there concrete, and be preserved in its metallic state. It is still more effectually detained by certain metallic bodies, as copper, or iron; with which the zinc, when thus applied, unites more readily and perfectly than it can be made to do by any other means.

1243
Oil from flowers of zinc by Mr Homberg. Homberg pretended to obtain an oil from the flowers of zinc, by dissolving them in distilled vinegar, and then distilling the solution in a glass retort. At first a quantity of phlegm arose; then the superfluous acid; and at last an empyreumatic oil. This last, which Homberg imagined to proceed from the flowers of zinc, Newmann very justly attributes to the distilled vinegar.

1244
Another by Mr Hellot. An oil of another kind was obtained by Mr Hellot from the above solution, by digesting the ash-coloured residuum, which remained after the distillation, with the acidulous phlegm which came over, for eight or ten days; distilling the tincture to dryness; and repeating the extraction with the distilled liquor, till the quantity of dry extract thus obtained was very considerable. This resin-like matter, distilled in a retort with a stronger fire, yielded a yellowish liquor, and a white sublimate. The liquor discovered no mark of oil; but, upon being passed upon the sublimate, immediately dissolved it, and then exhibited on the surface several drops of a reddish oil. Some of this oil was taken up on the point of a pencil, and applied to gold and silver-leaf. In twenty-four hours, the parts touched appeared, in both, equally dissolved.

1245
Zinc with other metals. Zinc does not unite in fusion with bismuth, or the semimetal called *nickel*. It unites difficultly with iron; less so with copper; easier with the other metals. It renders iron or copper more easily fusible; and, like itself, brittle whilst hot, though considerably malleable when cold. It brightens the colour of iron almost into a silver hue, and changes that of copper into a yellow or gold colour. It greatly debases the colour of gold; and renders near an hundredth part of that most ductile metal brittle and untractable. A mixture of equal parts of each is very hard, white, and bears a fine polish; hence it is proposed by Mr Hellot for making specula. It is not subject to rust or tarnish in the air, like those metals whose basis is copper. It improves the colour and lustre of lead and tin, renders them firmer, and consequently fitter for several mechanic uses. Tin, with a small proportion of zinc, forms a kind of pewter. Lead will bear an equal weight, without losing too much of its malleability. Maoluin observes, that arsenic, which whitens all other metals, renders zinc black and friable; that when the mixture is performed in close vessels, an agreeable aromatic odour is perceived on opening them; that zinc amalgamated with mercury, and afterwards recovered, proves whiter, harder, and more brittle than before, and no longer crackles on being bent.

1247
Deflagration of zinc with other metals. Mixtures of zinc with other metals, exposed to a strong fire, boil and deflagrate more violently than zinc by itself. Some globules of the mixture are usually thrown off during the ebullition, and some part of the metal calcined and volatilized by the burning zinc;

N^o 74

hence this substance has been called *metallic nitre*. Gold itself does not entirely resist its action. It very difficultly volatilizes copper; and hence the sublimes obtained in the furnaces where brass is made, or mixtures of copper and zinc melted, are rarely found to participate of that metal. On melting copper and zinc separately, and then pouring them together, a violent detonation immediately ensues, and above half the mixture is thrown about in globules.

Zinc does not unite in the least with sulphur, or with crude antimony, which scorify all other substances except gold and platina; nor with compositions of sulphur and fixed alkaline salts, which dissolve gold itself. With nitre it deflagrates violently. Its flowers do not sensibly deflagrate; yet alkalize double their weight of the salt more readily than the zinc itself. The alkaline mass appears externally greenish, internally of a purple colour. It communicates a fine purple to water, and a red to vinegar. The acetous tincture inspissated, leaves a tenacious substance which soon runs in the air into a dark red caustic liquor, the alkahest of some of the pretended adepts.

§ 9. BISMUTH.

THIS semimetal, called also *tin-glass*, and by some naturalists *marcasita officinarum*, is somewhat similar to the regulus of antimony. It appears to be composed of cubes formed by the application of plates upon each other. Its colour is less white than that of regulus of antimony; and has a reddish tinge, particularly when it is exposed to the air. In specific gravity it approaches to silver; being nearly ten times heavier than water. It has no degree of malleability; breaking under the hammer, and being reducible by trituration to fine powder. It melts a little later than tin, and seems to flow the thinnest of all metallic substances. Bismuth is semivolatile, like all other semimetals. When exposed to the fire, flowers rise from it; it is calcined; and converted into a litharge and glass nearly as lead is: (See GLASS). It may even be employed, like that metal, in the purification of gold and silver by cupellation. (See REFINING). When in fusion, it occupies less volume than in its solid state: a property peculiar to iron among the metals, and bismuth among the semimetals. It emits fumes in the fire as long as it preserves its metallic form; when calcined or vitrified, it proves perfectly fixed.

Bismuth mingles in fusion with all the metalline substances, except regulus of cobalt and zinc. The addition of nickel, or regulus of antimony, renders it miscible with the former, though not with the latter. It greatly promotes the tenuity as well as facility of the fusion of all those metals with which it unites. It whitens copper and gold, and improves the colour of some of the white metals: mixed in considerable quantity, it renders them all brittle, and of a flaky structure like its own. If mixed with gold or silver, a heat that is but just sufficient to melt the mixture, will presently vitrify a part of the bismuth; which, having then no action on those perfect metals, separates, and glazes the crucible all round.

Promotes the fusion of all the metals.

Regulus of Antimony.

§ 10. *REGULUS of ANTIMONY.*1252
Appearance of a star on its surface.

THIS semimetal, when pure, and well fused, is of a white shining colour, and consists of laminæ applied to each other. When it has been well melted, and not too hastily cooled, and its surface is not touched by any hard body during the cooling, it exhibits the perfect figure of a star, consisting of many radii issuing from a centre. This proceeds from the disposition that the parts of this semimetal have to arrange themselves in a regular manner, and is similar to the crystallization of salts.

1253
Sublimable.

Regulus of antimony is moderately hard; but, like other semimetals, it has no ductility, and breaks in small pieces under a hammer. It loses $\frac{1}{4}$ of its weight in water. The action of air and water destroys its lustre, but does not rust it so effectually as iron or copper. It is fusible with a heat sufficient to make it red hot; but when heated to a certain degree, it fumes continually, and is dissipated in vapours. These fumes form what are called the *argentine flowers* of regulus of antimony, and are nothing but the earth of this semimetal deprived of part of its inflammable principle, and capable of being reduced to its reguline state by an union with this principle.

1254
Separation of the sulphur from antimony.

There are different methods of preparing the regulus of antimony; but all of them consist merely in separating the sulphur which this mineral contains, and which is united with the regulus. It is plain, therefore, that regulus of antimony may be made by an addition of any substance to crude antimony in fusion, which has a greater attraction for sulphur than the regulus itself has. For this purpose, alkaline salts have been employed, either previously prepared, or extemporaneously produced in the process, by a deslagration of tartar and nitre. By this means, the sulphur was indeed absorbed; but the *hepar sulphuris*, formed by the union of the sulphur and alkali, immediately dissolved the regulus, so that very little, sometimes none at all, was to be obtained distinct from the scoria. Metals are found to answer better than alkaline salts, but the regulus is seldom or never free from a mixture of the metal employed. The way of obtaining a very pure regulus, and in great quantity, is to calcine the antimony, in order to dissipate its sulphur; then to mix the calx with inflammable matters, such as oil, soft soap, &c. which are capable of restoring the principle of inflammability to it. This method was invented by Kunckel. Another, but more expensive way of procuring a large yield of very pure regulus, is, by digesting antimony in aqua regis, which dissolves the reguline part, leaving the sulphur untouched, precipitating the solution, and afterwards reviving the precipitate by melting it with inflammable matters.

1255
Regulus easily miscible with mercury.

There are considerable differences observed in the regulus of antimony, according to the different substances made use of to absorb the sulphur. When prepared by the common methods, it is found to be very difficultly amalgamated with mercury; but Mr Pott has discovered, that a regulus prepared with two or five parts of iron, four of antimony, and one of chalk, readily unites with mercury into an hard amalgam, by bare trituration with water. Marble and quicklime suc-

ceed equally well with chalk; but clay, gypsum, or other earths, have no effect.

Regulus of Antimony.

1256

Extemporaneous regulus with cawk.

One earthy substance, found in lead-mines, and commonly called *cawk*, has a very remarkable effect upon antimony. This is found in whitish, moderately compact, and ponderous masses; it is commonly supposed a spar; but differs from bodies of this kind, in not being acted upon by acids, (see n° 1068). If a lump of cawk, of an ounce or two, be thrown red hot into 16 ounces of melted antimony, the fusion continued about two minutes, and the fluid matter poured off, "you will have 15 ounces like polished steel, and as the most refined quicksilver." *Phil. Trans.* n° 110. Dr Lewis mentions his having repeated this experiment several times with success: but having once varied it by mixing the cawk and antimony together at the first, a part of the antimony was converted into a very dark black vitreous matter, and part seemed to have suffered little change; on the surface of the mass some yellow flowers appeared.

Regulus of antimony enters into the compositions for metallic speculums for telescopes, and for printing-types. It is also the basis of number of medicinal preparations; but many of these, which were formerly much esteemed, are found to be either inert, uncertain, or dangerous in their operation. When taken in substance, it is emetic and purgative, but uncertain in its operation; because it only acts in proportion to the quantity of solvent matter it meets with in the stomach; and if it meets with nothing capable of acting upon it there, the regulus will be quite inactive. For these reasons, the only two preparations of antimony now retained, at least by skilful practitioners, are the infusion of glass of antimony in wine and emetic tartar. For making the glass of antimony we have the following process. "Take a pound of antimony; reduce it to fine powder, and set it over a gentle fire; calcine it in an unglazed earthen pan, till it comes to be of an ash colour, and ceases to fume: you must keep it continually stirring; and if it should run into lumps, you must powder them again, and then proceed to finish the calcination. When that is done, put the calcined antimony into a crucible; set it upon a tile in a wind-furnace; put a thin tile on the top; and cover it all over with coals. When it is brought into fusion, keep it so in a strong fire for an hour: then put into it an iron rod; and when the melted antimony, which adheres to it, is transparent, pour it upon a smooth, hot, marble; and when it is cold, put it up for use. This is *vitrum antimonii*, or *stibium*."

1257

Glass of antimony.

This preparation is more violent in its effects than the pure regulus itself; because it contains less phlogiston, consequently is similar to a regulus partially calcined, and so more soluble. Hence it is the most proper for infusion in wine, or for making the tartar emetic. It is obviously, however, liable to great uncertainties in point of strength; for as the antimony is more or less strongly calcined, the glass will turn out stronger or weaker in its operation, and consequently all the preparations of it must be liable to much uncertainty. This uncertainty is very apparent in the strength of different parcels of emetic tartar: accordingly Mr Geoffroy found by examination of different emetic tartars, that an ounce of the weakest contain-

1258

Difference of strength in emetic tartars.

Regulus of Antimony.

1259 Pulvis algaroth the most proper material for emetic tartar.

1260 Objection to its use.

1261 Scheele's theory of the nature of pulvis algaroth.

1262 His receipt for making it cheap.

ed from 30 to 90 grains of regulus; an ounce of moderate strength contained about 108 grains; and an ounce of the strongest kind contained 154 grains. For these reasons, the author of the Chemical Dictionary recommends the pulvis algaroth as the most proper material for making emetic tartar; being perfectly soluble, and always of an equal degree of strength. Emetic tartar, as he justly observes, ought to be a metallic salt composed of cream of tartar saturated with the regulus of antimony; and M. Beaumé has shown such a saturation to be possible, and that the neutral salt crystallizes in the form of pyramids. They are transparent while moist; but by exposure to a dry air, they lose the water of their crystallization, and become opaque. The preparation of this salt, according to M. Beaumé, consists in mixing together equal parts of cream of tartar, and levigated glass of antimony: these are to be thrown gradually into boiling water; and the boiling continued till there is no longer any effervescence, and the acid is entirely saturated. The liquor is to be filtered; and upon the filter is observed a certain quantity of sulphureous matter, along with some undissolved parts of the glass of antimony. When the filtered liquor is cooled, fine crystals will be formed in it, which are a soluble tartar perfectly saturated with glass of antimony. He observes, that the dissolution is soon over if the glass is well levigated, but requires a long time if it is only grossly pounded.

The trouble of levigating glass of antimony, as well as the uncertainty of dissolving it, would render pulvis algaroth much preferable, were it not on account of its price; which would be a temptation to those in use to prepare medicines, to substitute a cheaper antimonial preparation in its place. This objection, however, is now in a great measure removed by Mr Scheele; who demonstrated that the pulvis algaroth is no other than regulus of antimony half calcined by the dephlogisticated marine acid in the corrosive sublimate made use of for preparing the antimonial caustic. If therefore we can fall upon any other method of dephlogisticating the regulus, we shall then be able to combine the marine acid with it; and by separating them afterwards, may have the powder of algaroth as good as from the butter of antimony itself. One of the methods of dephlogisticating the regulus is by nitre. Our author therefore gives the following receipt for the powder in question.

“Take of powdered crude antimony one pound; powdered nitre, one pound and an half; which, after being well dried and mixed, are to be detonated in an iron mortar. The hepar obtained in this manner is to be powdered, and a pound of it to be put into a glass vessel, on which first a mixture of three pounds of water and 15 ounces of vitriolic acid is to be poured, and afterwards 15 ounces of powdered common salt are to be added; the glass vessel is then to be put in a sand bath, and kept in digestion for 12 hours, during which period the mass is to be constantly stirred. The solution, when cool, is to be strained through linen. On the residuum one third of the above menstruum is to be poured, and the mixture digested and strained. From this solution, when it is diluted with boiling water, the pulvis algarothi precipitates, which is to be welledulcorated and dried.”

As regulus of antimony, like other metallic sub-

stances, is soluble in liver of sulphur, it happens, that, on boiling antimony in an alkaline ley, the salt, uniting with the sulphur contained in that mineral, forms an hepar sulphuris, which dissolves some of the reguline part. If the liquor is filtered, and saturated with an acid, the regulus and sulphur will fall together in form of a yellowish or reddish powder, called *golden sulphur of antimony*. If the ley is suffered to cool, a like precipitation of a red powder happens. This last is called *kermes mineral*.

Nitre deflagrates violently with antimony, consuming not only its sulphureous part, but also the phlogiston of the regulus: and thus reduces the whole to an inert calx, called *antimonium diaphoreticum*. If equal parts of nitre and antimony are deflagrated together, the sulphureous part is consumed, as well as part of the inflammable principle of the regulus. The metalline part melts, and forms a semivitreous mass, of a reddish colour, called *crocus metallorum*, or *liver of antimony*. It is a violent emetic, and was formerly used for making infusions in wine similar to those of glass of antimony; but is now disused on account of its uncertainty in strength. It is still used by the farriers: but the substance sold for it is prepared with a far less proportion of nitre; and sometimes even without any alkaline salt being added to absorb part of the antimonial sulphur. This crocus is of a dull red colour; and, when powdered, assumes a dark purple.

§ II. ARSENIC.

This substance, in its natural state, has no appearance of a metal, but much more resembles a salt, which, as has been already observed, it really is when deprived of its phlogiston. When united to a certain quantity of phlogiston, it assumes a metallic appearance; and in this state it is found, as Mr Bergman informs us, in Bohemia, Hungary, Saxony, Hercynia, and other parts; particularly at Alsatia in the mines called *St Marieux*. The masses in which it is found are frequently shapeless, friable, and powdery; but sometimes compact, and divided into thick convex lamellæ, with a needle-formed or micaceous surface: it takes a polish, but soon loses it again in the air. When fresh broken, it appears composed of small needle-like grains of a leaden colour, soon becoming yellow, and by degrees blackish; exceeding copper in hardness, though as brittle as antimony.

Reguline arsenic, whether found naturally or prepared by art, very readily parts with as much of its phlogiston as is sufficient to make it fly off in a white smoke; but this still retains a very considerable quantity of phlogistic matter, as is evident from its producing nitrous air by the affusion of nitrous acid, and from the experiments already related of the preparation of the acid of arsenic. This calx indeed is the form in which arsenic is most commonly met with. It is less volatile than the regulus; and by sublimation in a glass vessel assumes an opaque crystalline appearance from becoming white on the surface; but that which crystallizes in the bowels of the earth does not appear to be subject to any such change.

White arsenic, though a true metalline calx, may be mixed in fusion with the same metals which will unite with the regulus. This seems contrary to the general rule of other calces, which cannot be united with any

Arsenic.

1263 Golden sulphur of antimony and kermes mineral.

1265 Crocus metallorum.

1266 Arsenic found naturally in a metallic form.

1267 Regulus of arsenic easily converted into the common white kind.

1268 White arsenic may be mixed with other metals.

1269
Arsenic. metal in its metalline state; but it must be remembered, that by this operation the arsenical calx is reduced to a regulus by the phlogiston of the metal: whence, in all fusions of this kind, some scoræ rise to the top, consisting of the calcined metal and part of the white arsenic.

1270
Solution of arsenic in water, Eight parts of distilled water dissolve, by means of moderate heat, one part of calcined arsenic, and by boiling may be made to take up 15. The solution changes syrup of violets green, but the tincture of turnsole red. It is not changed by neutral salts, but slowly precipitates the solutions of metals, the arsenic united to the metalline calx falling to the bottom.—“It may be asked (says Mr Bergman), whether the whole of the arsenic, or only the arsenical acid, unites with the metallic calx, yielding the phlogiston to the menstruum of the other metal?” Certainly such a mutual commutation of principles does not appear improbable, if we consider only those cases in which the menstruum is vitriolic or nitrous acid: but as iron, for example, united with marine acid (which does not attract the phlogiston of white arsenic), as well as when it is joined to the nitrous acid, is precipitated, it would appear that the whole of the arsenic is united, at least in certain cases, to the metallic calces.

1271
And in spirit of wine. One part of arsenic is dissolved by 70 or 80 of boiling spirit of wine.

1272
In vitriolic acid. Arsenic dissolves partially in concentrated vitriolic acid, but concretes in the form of crystalline grains on cooling. These dissolve in water with much greater difficulty than the arsenic itself. On the blow-pipe they emit a white smoke, but form into a globule by fusion, which at first bubbles, but soon grows quiet, and is but slowly consumed even in a white heat. This fixity is occasioned by the acid carrying off the phlogiston of the arsenic, and thus leaving a greater proportion of its peculiar acid than what it naturally contains; and therefore the more frequently the operation is repeated, the more fixed the arsenic becomes, though it is scarce possible to dissipate the arsenical phlogiston as perfectly with this acid as with the nitrous; the effects of which have been already particularly mentioned.

1273
In marine acid. The marine acid, which naturally contains phlogiston, dissolves about one-third of its weight of arsenic, a great part of which separates spontaneously on cooling in a state of saturation with the acid. This salt, which may be had in a crystalline form, is much more volatile than the former, readily subliming in a close vessel with a moderate heat; but is soluble with difficulty in boiling water. It is of a fine yellow colour, and scarcely differs from butter of arsenic, except in its degree of concentration. The nature of marine acid prevents it from disengaging the arsenical acid from the phlogiston of the femimetal, as will easily appear from what has been said concerning that acid. The arsenical acid, however, is easily made to appear by the addition of that of nitre, as will be understood from the directions given by Mr Scheele for the preparation of the acid of arsenic.

1274
Phlogisticated alkali cannot precipitate arsenic except from marine acid. Arsenic is not precipitated from its solution in vitriolic and nitrous acids by the phlogisticated alkali, which yet very readily precipitates all other metals. From the marine acid, however, it is precipitated by its means of a white colour; but unless the solution be very

acid, the addition of mere water will throw down a precipitate of the same colour.

1275
Dephlogisticated marine acid deprives arsenic of its inflammable principle; so that in the distilling vessel we find water, acid of arsenic, and marine acid, regenerated.

1276
Arsenic is dissolved by its own acid, and forms crystalline grains with it as well as with that of fluor and borax. Saccharine acid dissolves it likewise, and forms prismatic crystals; and a similar salt is also formed by the acid of tartar. Vinegar, and the acids of vinegar and phosphorus, form with it crystalline grains, which are scarcely soluble in water.

1277
Solutions of fixed alkali dissolve arsenic; and, when loaded with it, form a brown tenacious mass, called *liver of arsenic*. The arsenic is partly precipitated by mineral acids, though part of it gradually loses its phlogiston, and adheres more tenaciously. Solution made with volatile alkali seems to effect this decomposition more readily, as no precipitation is made by acids. Limpid solution of saline hepar, dropped into a solution of white arsenic, floats upon the surface in form of a grey stratum, which at length disturbs the whole liquor.

1278
By the assistance of heat solutions of arsenic attack some of the metals, particularly copper, iron, and zinc; the solutions of the two last yielding crystals by evaporation. No alteration is made on these compounds by alkaline salts or by acids: volatile alkali does not discover the copper by changing the colour of the solution blue; nor does the phlogisticated alkali throw down any blue precipitate from the solution of iron. The reason of this is the superabundance of phlogiston in the solutions; for the arsenical acid takes up all metals: when united with copper, it shows a blue colour with volatile alkali; and when united with iron, it lets fall a Prussian blue in the usual way; but the quantity of phlogiston which converts the acid into white arsenic, prevents the appearance of these phenomena when the latter is made use of.

1279
Arsenic, either in its calcined or reguline state, may be united with sulphur; in which case it appears either of a red or yellow colour, according to the quantity of sulphur with which it is united. These compounds are spontaneously produced by nature; both of them sometimes pellucid and crystalline; with this difference, however, that the yellow seems to affect a lamellated, and the red a crystalline, form. These are called *red and yellow orpiment*, or realgar and orpiment; the specific gravity of realgar being about 3.225; of orpiment, 5.315. Both of these sublime totally with a moderate heat, unless when they happen to be mixed with other substances. They readily unite with those metals which form an union with the arsenic and sulphur of which they are composed. Silver mineralized by fusion with orpiment, forms a substance similar to what is called the red ore of that metal. Iron, in conjunction with orpiment, assumes a white, polished, and metallic appearance, similar to that of the white or arsenical pyrites; and by various combinations of these substances with metals of different kinds, many of the natural metalline ores may be produced.

1280
Nitre, when treated with mineralized arsenic, decomposes it, and throws down a precipitate of arsenious acid.

Arfenic.

tonates partly with the sulphur, and partly with the phlogiston of the arsenic; the alkaline basis of the salt either forming sal polychrest with the acid of the sulphur, or uniting with the alkali, and forming the neutral arsenical salt. By the addition of fixed alkali in proper quantity, either to orpiment or realgar, and then exposing the mixture to a subliming heat, nitre retains the sulphur, but lets go the greatest part of the arsenic; the hepatic mass, however, retains a small quantity of the latter; and if there is much alkali, scarce any of the arsenic arises.

1281
Butter of
arsenic.

On distilling orpiment with twice or thrice its quantity of corrosive sublimate, two liquids arise which refuse to unite; and at length, on augmenting the heat, a cinnabar arises. A butter of arsenic is found at the bottom of the receiver, of a ferruginous brown colour, but pellucid: in the open air it first sends forth a copious fume of a white colour, and then gradually attracts the moisture of the atmosphere, by which it is precipitated. It is remarkable that it unites so slowly with marine acid, that they seem to repel one another; nor can they be made to unite beyond a certain degree. By the affusion of distilled water, a white powder will be precipitated, which, though ever so well washed, retains some acidity; for a portion of butter of antimony is produced by distillation, as is likewise true of the pulvis algaroth. The smoke has a peculiar penetrating smell, somewhat similar to that of phlogisticated vitriolic acid, and lets fall white flowers. The liquor which swims above, and which, by chemical authors, has been compared to oil, is yellowish and pellucid, separating a white arsenical powder by the addition of water and spirit of wine. It is not affected by the stronger acids; but effervesces, and lets fall a precipitate, with alkalies. On keeping it with a cucurbit with a long neck unstopped, white flowers gradually concrete round the orifice, which are lax, and sometimes approaching to a crystalline form. And lastly, by spontaneous evaporation, pellucid crystals appear at the bottom of the liquor, which are soluble in water with great difficulty; but when dissolved, precipitate silver from nitrous acid, and let fall some arsenic on the addition of an alkali. When put into lime water, a cloud slowly surrounds them: on being exposed to the fire, they totally sublime without any arsenical smell, without decrepitation, or losing their transparency; but if ignited phlogistic matter comes in contact with them, the arsenical smell instantly appears. No traces of mercury are to be found in this liquor by treating it either with alkali or copper; not the slightest precipitation is made by it on being dropped into a solution of terra ponderosa in the marine acid: from all which it appears, that this liquor is only a very dilute butter of arsenic, containing less of the mercury on account of the quantity of water it has. The butter contains the acid in its most concentrated state, and is therefore loaded with a larger quantity of arsenic: the former liquor will therefore be obtained in much larger quantity, by setting the mixture of corrosive sublimate and arsenic to stand a night in a cellar, or moistened with water, before it be subjected to distillation. As the common marine acid can dissolve only a determined quantity of the butter, it naturally follows, that what remains after complete saturation should totally refuse to mix. The acid,

rine acid.

1283.
Oil of ar-
senic.

however, when too much diluted, precipitates the butter; but in proportion to its strength it dissolves a greater quantity.

Arfenic mineralized by sulphur is not dissolved by water, but is affected by the different acids, according to the particular circumstances of each. Nitrous acid and aqua-regia act most powerfully; the former soon destroys the red colour of the realgar, and converts it into yellow orpiment; its primary action being to calcine the arsenic, without affecting the yellowness of the sulphur. It makes no change on the colour of orpiment. Aqua-regia, by long digestion, takes up the arsenic, and leaves the sulphur at the bottom; and hence we may find out the proportions of the two ingredients. Some dexterity, however, is necessary in performing this operation with accuracy; for if, on the one hand, the menstruum be too weak, part of the arsenic will remain undissolved; and if, on the other, it be too strong, part of the sulphur will be decomposed; for strong nitrous acid is capable of decomposing sulphur by long digestion, having a greater attraction for phlogiston than the vitriolic acid itself. The colour of the residuum ought to be grey; for as long as any yellow particles remain, it is a sign that some of the arsenic also remains. If any iron be present in the compound, it is all dissolved, by reason of the superior attraction of the acid for it, before any of the arsenic is taken up, unless it shall have been calcined either by the access of air and heat employed in the operation, or by the too great power of the menstruum.

The pure regulus of arsenic may be obtained artificially from white arsenic, either by sublimation with oil, black flux, or other phlogistic materials; or by melting it with double its weight of soap and potashes; or lastly, by precipitation by means of some other metal, from orpiment or sandarack melted with sulphur and fixed alkali. By the first of these methods it is obtained in a crystalline form, octohedral, pyramidal, or even prismatic. Mr Bergman mentions a natural regulus of arsenic, named *mispickel*, which along with some sulphur contains a large quantity of iron united with the regulus into a metallic compound; but tho' the iron sometimes amounts to $\frac{1}{2}$ or even $\frac{2}{3}$ of the whole, it nevertheless remains untouched by the magnet. When ignited, it sends forth an arsenical smell, and soon becomes obedient to the magnet, even though the operation be performed on a tile without any additional phlogiston; it melts easily in an open fire, and in close vessels the greater part of the regulus sublimes, leaving the iron at the bottom.

The pure regulus of arsenic is vastly more volatile than any other metal, and therefore cannot be melted. It begins to send forth a visible smoke in 180° of the Swedish thermometer, and is capable of inflammation; but in order to inflame it, it must be thrown into a vessel previously heated to a sufficient degree, otherwise it will be sublimed. The flame is of an obscure whitish blue, diffusing a white smoke and garlic smell. In close vessels it retains its metallic form, and may be sublimed of any figure we please.

Regulus of arsenic unites with many of the metals, but destroys the malleability of those with which it enters into fusion. It renders those more easy of fusion which are melted with difficulty by themselves; but tin, the most easily fusible of all the metals, be-

tals.

Arfenic. comes more refractory by being united with arfenic. This metal acquires a permanent and shining whiteness by its union with regulus of arfenic, and is able to retain half its own weight of the arfenical metal. The other white metals, become grey by fusion with this semimetal, platina only excepted. Gold fused in a close vessel with regulus of arfenic, scarcely takes up $\frac{1}{80}$ of its weight; silver $\frac{1}{4}$; lead $\frac{1}{8}$; copper $\frac{1}{8}$; and iron more than its own weight. The magnetic property of this last metal is destroyed by a large quantity of regulus, though the exact proportion which destroys it can scarcely be determined, as some of the iron is always taken up by the scoria; but according to Mr Bergman, less than an equal quantity is certainly sufficient. Bismuth retains $\frac{1}{17}$ of its weight; zinc $\frac{1}{7}$; regulus of antimony $\frac{1}{8}$; and manganese an equal quantity. Nickel and regulus of cobalt take up a large quantity; but how much cannot be determined, as it is next to impossible to procure any of those metals in a state of perfect purity. In a sufficient degree of heat, and by a triture of several hours, regulus of arfenic takes up about $\frac{1}{2}$ of its own weight of mercury, forming an amalgam of a grey colour.

1289
May be expelled by heat from all the metals with which it is united.

1290
Effects of it upon alkaline salts and nitre.

1291
Decomposes corrosive sublimate.

1292
Converted into white arsenic by the vitriolic acid.

Regulus of arfenic, by reason of its volatility, may be expelled from all the metals with which it is united; but, in flying off, it generally carries along with it some of the metal with which it is united, gold and silver not excepted, if the degree of heat be great and very suddenly applied. Platina, however, perfectly resists the volatilization; and, by reason of its refractory nature, even retains a portion of the arfenic.

This semimetal cannot be united by fusion with alkaline salts until the phlogiston is considerably diminished, and the regulus approaches to the nature of pure arfenical acid. By adding regulus therefore to nitre in fusion, a detonation ensues, the phlogiston of the former is totally destroyed, and the acid uniting with the alkali of the nitre forms a neutral arfenical salt, similar to that made with white arsenic and nitre. By distillation with dry acid of arfenic, the regulus sublimes before it can be acted upon by the acid; but when thrown into the acid in fusion, soon takes fire, and sends forth a white smoke: for the acid, being in this instance deprived of its phlogiston, separates that principle from the regulus, and unites with it in such quantity as to regenerate white arsenic; while, on the other hand, the regulus, by this operation, is so far deprived of its phlogiston as to appear in the form of a calx. By distillation with corrosive sublimate, a smoking butter, and small quantity of mercurius dulcis and running mercury, are procured; which happens in consequence of a double elective attraction; the regulus of arfenic yielding its phlogiston to the base of the corrosive sublimate, which being thus really calcined, reduces the former to perfect mercury, while the marine acid takes up the calx of arfenic. The regulus of arfenic readily unites with sulphur, and forms the same red and yellow compounds that have already been mentioned when speaking of white arsenic; it is soluble in hepar sulphuris, but may be precipitated by every other metal which can unite with the hepar.

Regulus of arfenic is not affected by the vitriolic acid, unless when concentrated and assisted by heat. The inflammable part of the regulus which phlogisticates the acid flies off, so that the remainder assumes

the nature of white arsenic, and exhibits the same properties with menstrua as any other metallic calx: the same holds good with nitrous acid, except that it attracts the phlogiston more vehemently. Marine acid has little or no effect except when boiling.

Regulus of arfenic precipitates certain metals dissolved in acids, such as gold and platina dissolved in aqua regia, as well as silver and mercury in vitriolic and nitrous acids. Silver generally appears in beautiful polished spiculæ, like the arbor Dianæ; but if the arfenic be suffered to stand long in the nitrous solution but little diluted, the silver spiculæ are again dissolved, the arfenic in the mean time being dephlogisticated. Solutions of bismuth and antimony are scarcely rendered turbid. Iron may be separated from regulus of arfenic by digestion with marine acid, or with aqua regia; neither of which will touch the arfenic, as long as any iron remains; but in order to succeed in this operation, subtil pulverisation is necessary as well as a just quantity and strength of the menstruum. Heat must also be carefully avoided. The regulus is also dissolved by hepar sulphuris and by fat oils, the latter forming with it a black mass like plaster.

§ 12. COBALT.

REGULUS of cobalt, or more properly pure cobalt itself (what we have under the name of *cobalt* being only a calx of the regulus), is a semimetal of a reddish white colour, close-grained, so as to be easily reducible to powder, about 7.7 of specific gravity, and forming itself into masses of a needle-like texture, placed upon one another. It is seldom or never found native, but almost always calcined and united with arfenic, the arfenical acid, sulphur, iron, &c. The zaffre used in commerce is an impure and grey calx of cobalt. When mixed with three times its weight of pulverized flints, and exposed to a strong fire, it melts into glass of a dark blue colour, called *smalt*, used in tinging other glasses, and in painting. With three times its weight of black flux, a small quantity of tallow and marine salt, it affords the semimetal known by the improper name of *regulus of cobalt*; but the reduction is very difficult. For this purpose a large quantity of flux must be made use of, and the crucible kept a considerable time in a white-red heat, that the matter may become very fluid, and that the scoria may be completely fused into a blue glass; at which period the cobalt sinks in the form of a button to the bottom.

Cobalt melts in a strong red heat, is very fixed in the fire, and it is uncertain whether it can be volatilized in close vessels. When suffered to cool slowly, it crystallizes in needle-shaped prisms, placed one upon the other, and united in bundles, having a considerable resemblance to masses of basaltes separated from each other: in order to succeed in this crystallization, however, the cobalt must be melted in a crucible till it begins to boil, and, when the surface of the metal becomes fixed on being withdrawn from the fire, the vessel is then to be inclined; that which still remains fluid runs out, and the portion adhering to the lumps formed by the cooling of the surface is found covered with crystals.

This semimetal, exposed to the atmosphere, becomes covered with a dull pellicle, and undergoes a spontaneous calcination; but it may easily be calcined

in any quantity by exposing it in powder in a shallow vessel, under the muffle of a cupelling furnace, and stirring it now and then to expose fresh surfaces to the air. After being kept red hot for some time, this powder loses its splendor, increases in weight, and becomes black, the calx being convertible, by a most violent heat, into a blue glass. By fusion it combines with vitrifiable earths, forming with them a beautiful blue glass extremely fixed in the fire; whence it is of the greatest use in enamel-painting, porcelain-painting, &c. The action of terra ponderosa, magnesia, and lime, on cobalt, is not known. Alkalies manifestly alter it; but in what respect is not known.

Cobalt dissolves in concentrated vitriolic acid, when assisted by a boiling heat; the acid evaporating almost entirely in the form of sulphureous gas. The residuum is then to be washed; a portion of it dissolves in the water, and communicates a greenish colour to it when warm, which changes to a rose colour when cold. M. Beaumé affirms, that by sufficiently evaporating the vitriolic solution of cobalt, two sorts of crystals are obtained; one white, small, and cubical; the other greenish, quadrangular, six lines in length, and four in breadth. These last he only considers as the true vitriol of cobalt; the former being produced by certain foreign matters united to it. The crystals most commonly obtained have the form of small needles, and may be decomposed by fire, leaving a calx of cobalt not reducible by itself. They may likewise be decomposed by all the alkalies, by terra ponderosa, magnesia, and lime. According to Fourcroy, 100 grains of cobalt, dissolved in the vitriolic acid, afford, by precipitation with pure mineral alkali, 140 grains of precipitate; by the same alkali aerated, 160 grains. Diluted vitriolic acid acts on zaffre, and dissolves a part, with which it forms the salt already described.

Nitrous acid acts upon the semimetal with that violence which is its general characteristic; and the solution, when nearly saturated, appears either of a rosy brown or bright green colour. By strong evaporation it yields a salt in small needles joined together; which is very deliquescent, boils upon hot coals without detonation, and leaves a calx of a deep red colour. It is decomposed by the same substances as the former, and by excess of alkali the precipitate disappears.

Muriatic acid, assisted by heat, dissolves cobalt in part, but has no effect upon it in the cold. It acts more strongly on zaffre, forming a solution of a reddish brown, which becomes green by being heated. By evaporation it yields a very deliquescent salt in small needles, which becomes green when heated, and is soon after decomposed. Aqua-regia dissolves the metal rather more easily than the marine acid, but less so than the nitrous. The solution has been long known as a *sympathetic Ink*.

Cobalt is not dissolved directly by the acid of borax; but when a solution of this salt is mixed with a solution of cobalt in any of the mineral acids, a double decomposition takes place; the alkaline basis of the borax uniting with the acid which held the cobalt in solution; and the calx, combining with the sedative salt, falls to the bottom in form of an insoluble precipitate.

This semimetal is calcined by being heated to ignition with nitre. One part of cobalt, and two or three

of dry nitre, well powdered and mixed, when thrown into a red-hot crucible, produce small scintillations; a portion of the cobalt being converted into a calx of a red colour, more or less deep, and sometimes of a green. Sal ammoniac is not decomposed, by reason of the little attraction there is between the metal and muriatic acid. M. Bucquet, who made the experiment with great care, could not obtain a particle of volatile alkali. Sulphur does not unite with it but very difficultly, and the combination is promoted by liver of sulphur. Thus a kind of artificial ore may be produced, the grain of which will be finer or closer, and its colour whiter or yellower, in proportion to the quantity of sulphur in the mixture. M. Beaumé observes, that this compound cannot be decomposed by acids, and that fire cannot destroy all the sulphur.

§ 13. NICKEL.

This was first discovered to be a semimetal of a peculiar kind by Cronstedt, in the years 1751 and 1754, who procured it in the form of regulus from its ore, but without being able to reduce it to a sufficient degree of purity; which indeed has not yet been done by any chemist. M. Bergman has laboured most in this way, though even he has not reduced it to the purity of other metallic substances. His experiments were made with some regulus made by M. Cronstedt, and whose specific gravity was to that of water exactly as 7.421 to 1. His attempts to purify it were made,

I. By Calcination and Scorification.

Nine ounces of powdered nickel were exposed for six hours, in several portions, to a most violent heat, under the dome of an assay furnace. Thus the arsenic was first dissipated with a fetid smell, after which the odour of sulphur became perceptible; after this a white smoke arose without any smell of garlic, and which, according to our author, arose probably from the more dephlogisticated part of the arsenic which now began to sublime. The heaps (we suppose after the matter had been poured out of the dishes, and yet retaining a great deal of heat), when hot, began to swell, and green vegetations arose from all the surface, resembling some kinds of moss, or the filiform lichen; a ferruginous ash-coloured powder remained at bottom; and 0.13 of the whole were dissipated during the operation. Half an ounce of this calx, fused in a forge for four minutes, along with three times its weight of black flux, yielded a regulus reticulated on the surface; the areola of a hexangular figure, with very slender striæ, diverging from a centre, full of little tubercles; it weighed 0.73 of half an ounce; was obedient to the magnet; and, when scorified with borax, left a blackish glass.

By a second roasting the regulus again emitted a garlic smell; afterwards a visible fume without any smell, with vegetations as before. The roasted powder, reduced with black flux as before, still emitted a smell of arsenic; but, on repeating the fusion with the calx and borax, nothing but some obscure signs of cobalt appeared. A third calcination seemed to have much dissipated the arsenic, as it now emitted but little of that kind of smell; the vegetations were also gone; and the matter had rather a ferruginous than a green

Nickel. green colour. Nearly the same phenomenon appeared after reduction in a fourth operation.

On performing the reduction with lime and borax, the regulus, when first melted, lost much of its ferruginous matter, which adhered to the black scoria; it soon acquired an hyacinthine colour, without any remarkable mixture of cobalt, was little obedient to the magnet, and its specific gravity was somewhat diminished, being now only 7.0828.

By a fifth calcination, gradually adding a quantity of powdered charcoal while the matter continued red hot, a prodigious quantity of arsenic, imperceptible before, flew off in the form of vapour; the arsenical acid being thus furnished with as much phlogiston as was necessary to make it rise in fume. The regulus was treated in this manner until no more arsenical smoke could be perceived; it was now of a lamellated and tenacious texture when reduced, but still diffused the arsenical odour on being removed from the fire. The roasting was therefore repeated a sixth time, and continued for ten hours; the addition of powdered charcoal continued to dissipate the arsenic in invisible vapours, which yet were perceptible by the smell; the colour of the metallic calx was obscurely ferruginous, with a mixture of green scarcely visible. On reducing the regulus with equal parts of white flux, lime, and borax, a semiductile regulus was obtained, highly magnetic, and soluble in nitrous acid, to which it communicates a deep green colour; a blackish mass remained, which afterwards became white, and when laid on a burning coal, flies off without any remarkable arsenical smell. The regulus being then six times fused with lime and borax, the scoria resembled the hyacinth in colour, and the metallic part was surrounded with a green calx. The regulus, as before, was magnetic and semi-malleable. Lastly, it was exposed for 14 hours to a very strong heat; when the powdered charcoal was added by degrees without any dissipation of arsenic or loss of weight; the colour of the roasted powder was ferruginous, with a very slight tinge of green. On reduction, a very small globule, still magnetic, was found among the scoria.

II. By Sulphur.

1308
Effects of
Sulphur and
borax. Eight hundred parts of Cronstedt's regulus of nickel, fused with sulphur and a small quantity of borax, yielded a mineralized mass of a reddish yellow, whose weight amounted to 1700. On exposing one half of this to the fire, it began to grow black; on which the heat was augmented until vegetations appeared; the remaining calx weighed 652. Melting this part with borax, and the other which had not been exposed to the fire, a sulphurated regulus of a whitish yellow colour was obtained, weighing 1102. The same regulus, calcined for four hours, was first covered with vegetations, and then, on the addition of powdered charcoal, diffused an arsenical odour; the metallic calx was green, and weighed 1038. A whitish yellow regulus was obtained, semiductile, highly magnetic, and extremely refractory, weighing 594. By fusion with sulphur a second time, it weighed 816; one half of which roasted to greenness, united by means of fire to the other half still sulphurated, weighed 509, and was almost deprived of its magnetic quality. A calcination of four hours, during which phlogiston was ad-

ded, dissipated a considerable quantity of arsenic; the powder put on an ash-colour, somewhat greenish, was in weight 569; and by reduction yielded a regulus whose surface was red, and which, on breaking, appeared of a white ash-colour, very friable, and weighing 432; the specific gravity 7.173.

On mineralizing the regulus a third time with sulphur, adding charcoal as long as any vestige of arsenic remained, which required a violent calcination of 12 hours, the remaining powder was of an ash-green colour, and weighed 364; but the regulus obtained by means of a reduction effected by the most violent heat in a forge for three quarters of an hour, was so refractory, that it only adhered imperfectly to the scoria, which were of a distinct hyacinthine colour; nor could it be reduced to a globule by means of borax, though urged by the same vehemence of fire. The absolute gravity of this regulus was 180; its specific gravity 8.666. Its magnetic virtue was very remarkable; for it not only adhered strongly to the magnet, but to any other piece of iron; and the small pieces of it attracted one another. It had a considerable ductility, was of a whitish colour, mixed with a kind of glittering red; dissolved in volatile alkali, yielding a blue solution, and a green one in nitrous acid.

An hundred parts of the same regulus, beaten out into thin plates, were covered, by a calcination of four hours, with a crust apparently martial, having under it a green powder, and within it a nucleus consisting of reguline particles still unchanged; the weight being increased by 5. The friable matter, reduced to powder, put on a brownish-green colour; and after a calcination of four hours more, concreted at the bottom in form of a friable black crust, strongly magnetic, and weighing 100. No vestiges of arsenic were discovered by a succeeding operation, in which charcoal was added; nor was the magnetic power destroyed, but the weight was increased to 105, and the colour somewhat changed. By fusion for an hour with lime and borax, this powder yielded a regulus of an angular structure, red, semiductile, and altogether magnetic; the specific gravity being 8.875. The same globule, dissolved in aqua-regia, was precipitated by green vitriol, as if it had been loaded with gold; but the precipitate was readily soluble in nitrous acid. Most of the reguli showed no signs of precipitation with green vitriol.

III. With Hepar Sulphuris.

1309
Effects of
hepar sulphuris. Fifty-eight parts of regulus of nickel, which had been sulphurated before, being fused with 1800 parts of saline hepar sulphuris, then dissolved in warm water, filtered through paper, and precipitated by an acid, yielded a powder, which, by calcination till the sulphur was driven off, appeared of an ash-colour, and weighed 35. The insoluble residuum, deprived of its sulphur by means of fire, was likewise of an ash-colour, and weighed 334. On reducing this regulus by means of the black flux, a friable regulus was obtained, which had a very weak magnetic property; but, on fusion with borax, this quality was augmented. On mixing and melting together equal parts of calx of nickel, gypsum, colophony, and white flux, a powdery, squamous, and reguline mass was produced; which, by fusion with borax, afforded a regulus possessing the properties.

Nickel.

Nickel.

properties of nickel, but not entirely destitute of cobalt, which obeyed the magnet, and did not part with its iron even after two solutions in the nitrous acid, and various reductions by fusion with borax; the sulphur was also retained with great obstinacy.

On dissolving regulus of nickel by fusion, in hepar sulphuris made with fixed alkali, adding a quantity of nitre sufficient only to destroy a small part of the hepar, the regulus which had been suspended by it was separated, and fell to the bottom. On examining this regulus, it appeared more pure, and generally deprived of cobalt, but still containing iron. In like manner nickel is always very distinctly precipitated by regulus of cobalt, as this latter is attracted more powerfully by the hepar sulphuris. When dissolved by fusion with hepar sulphuris, this semimetal may be precipitated by adding iron, copper, tin, or lead, and even by cobalt: the regulus obtained is indeed scarcely ever attracted by the magnet; but we are not from thence to conclude that it does not contain any iron; for when the heterogenous matters, which impede its action, are properly removed, it then acknowledges the power of the magnet very plainly.

IV. By Nitre.

1310
Of nitre.

One part of Cronstedt's regulus was added to twelve of nitre ignited in a crucible, and kept red-hot for about an hour. Some weak flashes appeared first; then a large quantity of arsenic was emitted; and, lastly, the sides were covered with a blue crust occasioned by the cobalt, a green matter remaining at bottom. This, fused again for an hour, with twelve parts of nitre, tinged the internal sides of the vessel of a green colour; and, lastly, a brownish green mass, much less in quantity than in the former operation, was left at the bottom. This green matter, treated in the same way for two hours a third time, left a grey scoria at the bottom, which yielded no regulus with black flux.

Another portion of the same regulus, treated in the same way with nitre, was dissolved, and became green; yet on being freed by ablution from the alkaline salt, it yielded no regulus with black flux, but only scoria of an hyacinthine colour mixed with blue, tinging nitrous acid of a green colour, concreting into a jelly, and on evaporation leaving a greenish calx behind.

Another portion of Cronstedt's regulus was kept some hours in the crucible with 16 parts of nitre; by which means all the arsenic was first separated; then the phlogisticated nitrous acid; and, lastly, the sides of the vessel were penetrated by a kind of green efflorescences. The mass, after being washed with water, was of a dilute green colour, and tinged borax of a greenish brown. A green powder was still yielded, after treating this in the same manner with 12 parts of nitre; and on reducing it with one-half black flux, one-eighth borax, and as much lime, a yellowish white regulus, both magnetic and malleable, was obtained, possessing all the properties of nickel. Its specific gravity was 9.000; the phlogistic ingredient was used in small quantity, that the iron might, if possible, enter the scoria.

1311
Nitre capable of separating all the cobalt from nickel.

It having appeared from this and some other experiments, that nitre was capable of discovering the smallest quantity of cobalt contained in nickel, the products of the former operations were now subjected

N^o 74.

to its action. The regulus produced by repeated scorification thus became a little blue; that dissolved in volatile alkali (to be afterwards particularly mentioned) discovered a considerable quantity of cobalt; nor was there any one which did not thus discover more or less of that ingredient by this trial.

Nickel.

V. By Sal Ammoniac.

A calx of nickel, so much freed from cobalt that it did not tinge borax in the least, mixed with twice its weight of sal ammoniac, yielded, by sublimation with a strong red heat, two kinds of flowers; one, which rose higher than the other, was of an ash colour; the other white. The bottom of the glass was stained of a deep hyacinthine colour: the residuum was divided into two strata; the upper one yellow, scaly, and shining like mosaic gold. With borax it afforded an hyacinthine glass, but not regulus; and in a few days liquefied in the air, acquiring a green colour and the consistence of butter. The residuum showed the same properties with calx of nickel; and the green solution showed no vestiges of iron with galls, but became blue with volatile alkali; which was also the case with the flowers. The lower stratum contained a calx, blackish on the upper part, but of a ferruginous brown in the under, with a friable and scarcely magnetic regulus, of a reddish white. The blackish calx yielded an hyacinthine glass with borax. Part of this stratum sublimed with twice its quantity of sal ammoniac; and with the same degree of heat as before, yielded flowers of a very fine white, with a residuum of ferruginous brown, greenish on the upper part towards the sides of the vessel, the bottom being stained of an hyacinthine colour as before. Twenty parts of sal ammoniac being added to a part of the inferior stratum reduced, the whole was sublimed in a retort; a blackish powder remained, which became green by calcination, and of an hyacinthine colour by scorification, as did also the bottom of the containing vessel. The sublimation being twice repeated, using a double quantity of sal ammoniac each time, the calx became at length very green, dissolving with the same colour in the nitrous acid, and yielding by reduction a white, brittle, and very little magnetic regulus. In all these sublimations, it was observed, that the volatile alkali rose first; then sal ammoniac; and, lastly, a part of the marine acid was forced over by the violence of the heat.

1312
Effect of sal ammoniac.

VI. With Nitrous Acid.

Having obtained a salt by crystallization from nickel dissolved in nitrous acid, part of this was calcined with charcoal dust in a proper vessel, and during the operation a large quantity of arsenic was dissipated; a grey, semiductile, and magnetic regulus being obtained after reduction. A brittle regulus was obtained after a second solution, precipitation, and reduction; but by a third operation it became again semiductile and magnetic. By repeating this process a fourth and fifth time, the quantity became so much diminished that it could no longer be tried. In all these solutions, a blackish residuum appeared; which, when suffered to remain in the acid, grew white by degrees; but whenedulcorated and laid on a burning coal, exhaled a sulphureous smoke, and left a black powder soluble in the nitrous acid.

1313
Effects of antimony.

VII. By

Nickel.

1314
Volatile
alkali.

VII. By Volatile Alkali.

Four hundred and eighty-seven parts of a calx of nickel, produced by dissolving Cronstedt's regulus in nitrous acid, and precipitating the solution by a fixed alkali, being immersed for 24 hours in a quantity of volatile alkali, yielded a residuum of fifty, having a blackish green colour. The solution, which was blue, by filtration and inspissation yielded a powder of a light blue colour, weighing 282; which, reduced with black flux, produced a white, semiductile, and highly magnetic regulus, weighing 35, whose specific gravity was 7.000. The scorix were of a light red; but when mixed with borax, put on an hyacinthine colour, and yielded a regulus weighing 30. The two reguli united together proved very refractory; so that the mass could not be melted by the blow-pipe, even with the addition of borax. It sent forth neither an arsenical nor sulphureous smell on the addition of charcoal-dust; but, on a succeeding reduction, yielded hyacinthine scorix; and the remaining flocculi, dissolved in nitrous acid, affording a very green solution, which, on the addition of volatile alkali, yielded a powder of the same colour.

From 50 parts of the blackish green residuum, 13 of a clear white, brittle, squamous, and little magnetic regulus, were obtained, the specific gravity of which was 9.333. At the bottom of the vessel was found a scoria of an obscurely blue colour, with the upper part hyacinthine. It was easily fused; and tinged borax, first blue, then of a hyacinth colour, upon which it became more strongly magnetic. By the assistance of heat it dissolved in nitrous acid, forming a solution of a beautiful blue colour. A black powder at first floated in the liquor, but became white, and fell to the bottom. After edulcoration it was for the most part dissipated, with a sulphureous smell, on being exposed to the fire; a little brown-coloured mass, soluble in volatile alkali, remaining at bottom. This solution was precipitated by phlogisticated alkali, and a powder thrown down of the colour of calx of nickel, which soon grew blue with volatile alkali.

1315 Nickel cannot be obtained in a state of purity. From all these experiments it appears, that nickel cannot be obtained in a state of purity by any means hitherto known. From every other substance, indeed, it may be separated, except iron; but this resists all the operations hitherto described, and cannot be diminished beyond certain limits. The magnet not only readily discovers its presence, but some portions of the regulus itself becomes magnetic; but the tenacity and difficulty of fusion, which increase the more in proportion to the number of operations, plainly show that there is no hope of separating the whole quantity, unless we suppose the regulus of nickel itself to be attracted by the magnet; and there is certainly a possibility that one other substance besides iron may be attracted by the magnet. The great difficulty, or rather impossibility, of obtaining it in a state of purity, naturally raises a suspicion of its not being a distinct semimetal, but a mixture of others blended together; and on this subject our author agrees in opinion with those who suppose it to be a compound of other metals. Indeed, Mr Bergman is of opinion, that "nickel, cobalt, and manganese, are perhaps no other than

VOL. IV. Part II.

modifications of iron." And in order to ascertain this, he made the following experiments.

1. Equal parts of copper, of the gravity of 9.3243, and iron of 8.3678, united by fusion with black flux, yielded a red mass, whose specific gravity was 8.5441; and which tinged nitrous acid first blue, then green, afterwards yellow, and at last of an opaque brown. 2. Two parts of copper and one of iron had a specific gravity of 8.4634; the mixture yielding first a blue, and then a green solution. 3. Equal parts of copper and iron, of the specific gravities already mentioned, with another part of cobalt whose gravity was 8.1500, yielded a metal of the gravity of 8.0300, imparting a brown colour to the solution. 4. Two parts of arsenic of 4.000, added to one of copper and another of iron, gave a brittle metal of 8.0468, which formed a blue solution. 5. One part of copper, one of iron, two of cobalt, and two of white arsenic, gave a brittle regulus of 8.4186; the solution of which was brownish, and separated in part spontaneously. 6. One part of copper, one of iron, four of cobalt, and two of white arsenic, formed a mass of 8.5714. The solution was somewhat more red than the former; and a similar effect took place on repeating the experiment, only that the specific gravity of the metal was now 8.2941. 8. One part of iron and four of white arsenic formed a metal which dissolved with a yellow colour; and, on the addition of Prussian alkali, immediately let fall a blue sediment. 9. One part of copper, eight of iron, sixteen of white arsenic, and four of sulphur, united by fire, on the addition of black flux, yielded a mass which, though frequently calcined and reduced, produced nothing but brown or ferruginous calces. It acquired a greenness with nitrous acid, but on the addition of phlogisticated alkali deposited a Prussian blue. 10. One part of iron was dissolved in six of the nitrous acid, and likewise separated by one part of copper and one of the calcined ore of cobalt, in the same quantity of the same acid. The whole of the solution of iron was then mixed with five parts of the solution of copper, whence a green and saturated nickel colour was produced; which, however, on the addition of three parts of the solution of cobalt, became evidently obscured. The alkaline lixivium dropped into this threw down at first a ferruginous brown sediment, the solution still remaining green: afterwards all the blue was precipitated; by which at first all colour was destroyed, but afterwards a red appeared, occasioned by the cobalt dissolved in the alkaline salt. The sediment, when reduced, yielded a regulus similar to copper, and at the same time ductile, which tinged both glass and nitrous acid of a blue colour. If a saturated solution of nickel be mixed with half its quantity of solution of cobalt, the green colour is much obscured; but four parts of the former, on the addition of three of the latter, put off all appearances of nickel. See the article NICKEL.

§ 14. Of PLATINA.

THE properties of this metal have not as yet been thoroughly investigated by chemists, and there is therefore some disagreement concerning them. Formerly it was supposed to be inferior in specific gravity to

gold; but now is generally allowed to be superior in that respect by little less than a fourth part; being to water in the proportion of 23 to 1 when perfectly freed from all heterogeneous matters. Mr Bergman says that its colour is that of the purest silver. The very small globules of it are extremely malleable; but when many of these are collected together, they can scarcely be so perfectly fused as to preserve the same degree of malleability. They are not affected by the magnet in the least, nor can they be dissolved in any simple menstruum excepting dephlogisticated marine acid. As it is commonly met with, however, platina has the form of small grains, its plates of a bluish black, whose colour is intermediate betwixt those of silver and iron. These grains are mixed with many foreign substances, as particles of gold, mercury, and blackish ferruginous, sandy grains, which by the magnifier appear scorified. The grains themselves, when examined by a magnifying glass, appear sometimes regular, sometimes round and flat, like a kind of button. When beat on the anvil, most of them are flattened and appear ductile; some break in pieces, and on being narrowly examined appear to be hollow, and particles of iron and a white powder have been found within them: and to these we must attribute the attraction of platina by the magnet; since, as we have already observed, pure platina is not attracted by it.

Mr Bergman, who carefully examined this metal, dissolved it first in aqua-regia composed of the nitrous and marine acid. The solution at first exhibits a yellow colour, but on approaching to saturation became red, and the redness increases as the liquor becomes more loaded with metal. Crystals are produced by evaporation of a deep red colour, generally in small angular and irregular grains, whose true shape cannot be discovered. Their appearance is sometimes opaque and sometimes pellucid. After these are once formed, they are extremely difficult of solution, requiring much more water than even gypsum itself for this purpose.—The solution is not precipitated by vegetable fixed alkali, nor does the latter affect the crystals, except very faintly by digestion with them in a caustic state. Aerated mineral alkali takes them up and grows yellow, but without depositing any thing, though it decomposes them at last by evaporating to dryness.

On the addition of a small quantity of vegetable fixed alkali, either mild or caustic, small red crystals soluble in water, and sometimes of an octohedral figure, are deposited. They are decomposed with difficulty by the mineral alkali, but not at all by the vegetable. If a larger quantity of salt is added at first, an insoluble spongy matter of a yellow colour is precipitated. Crystalline particles of the same kind are thrown down by an alkali saturated either with the vitriolic, nitrous, marine, or acetous acids, though all the platina cannot thus be separated from the menstruum.

Aqua-regia, composed of nitrous acid and common salt, dissolved the metal with equal facility as the former; only the solution was more dilute, and a yellow powder floated on the surface, a larger quantity being found at the bottom. On adding vegetable fixed alkali to the clear solution, a copious yellow powder, soluble in a large quantity of water, was deposited.

A powder, of a similar kind, was precipitated, though more slowly, and more of a crystalline nature; but mineral alkali, though used in much larger quantity, did not make any alteration. The collected powder was yellow, and agreed in property with that separated spontaneously in a former experiment.

On repeating the experiment with nitre and depurated spirit of salt, instead of nitrous acid and sea-salt, the platina was dissolved into gold-coloured liquor, a greenish coloured granulated matter falling to the bottom, and the finer part of the same rising to the top. After saturating the superfluous acid, a metallic calx, insoluble in water, was thrown down by the vegetable alkali. The green powder is soluble in water, and is of the same nature with the precipitate thrown down by the vegetable alkali.

Platina precipitated from aqua-regia by a sufficient quantity of mineral alkali, the precipitate washed and dissolved in marine acid, on the addition of vegetable alkali immediately lets fall a crystalline powder, as it does also with nitre and other salts, having the vegetable alkali for their basis. The case is the same with calx of platina dissolved in vitriolic acid. Nitrous acid also dissolves the calx of platina, but does not yield any distinct saline precipitate without the assistance of marine acid.—The above phenomena are likewise produced by the precipitate thrown down by the vegetable alkali after the saline powder has been deposited.

From these experiments our author concludes, 1. That the precipitate which is first thrown down, on the addition of vegetable alkali to solutions of platina, is a saline substance, and different from the calx of the metal. 2. That this saline precipitate is composed of calcined platina, marine acid, and vegetable alkali. 3. By means of vitriolic acid, a precipitate analogous to this may be obtained, composed of calcined platina, vegetable alkali, and vitriolic acid. 4. The whole solution of platina cannot be precipitated by vegetable alkali in form of a triple salt; but after passing a certain limit, a metallic calx in the usual way is produced.

As it has been denied by Margraaf and Lewis that mineral alkali is capable of separating platina from its acid, our author was induced to attend particularly to this circumstance. Having therefore tried the common solution with mineral alkali, he found that each drop excited a violent effervescence, and at last that a yellow spongy matter, affording a genuine calx of platina, was precipitated: this was more speedily effected by using the dry mineral alkali, which had fallen to powder of itself. To determine, however, the difference betwixt the two alkalies in a more accurate manner, he divided a very acid solution of platina into two equal parts. To one of these he added small portions of the vegetable, and to the other an equal weight of pieces of mineral alkali, waiting five minutes after every addition, till the effervescence should fully cease. After the first addition, small crystals appeared; in the former partly on the surface, and partly in the bottom; but in the latter no precipitate could be observed until 56 times the quantity of vegetable alkali had been added. The difference, however, was even greater than what appears from this experiment; for the vegetable alkali was crystallized, and therefore charged with the water necessary to its crystalline form;

¹³³⁰ Platina. form; whereas the mineral alkali was spontaneously calcined: and though, in equal quantities of these two alkalies, the purely alkaline parts are as 3 to 2, yet three parts of vegetable alkali saturated only 1.71 of this aqua-regia, while two of the mineral alkali took up about 2.6.

¹³³⁰ Effects of the volatile alkali.

The volatile alkali first throws down this metal in a saline form; the grains sometimes distinctly octohedral. Their colour is red when that of the solution is so, but yellow when the solution is more dilute. After saturating the superabundant acid, the same alkali precipitates the platina truly calcined. This precipitate is dissolved in water, though with difficulty, and may be reduced to more regular crystals by evaporation. These are dissolved by the mineral alkali; but hardly any signs of decomposition are to be observed, unless the yellow solution, evaporated to dryness, be again dissolved in water; for then the metallic calx rests at the bottom, and the solution is deprived of its yellow colour. The vegetable alkali has scarce any effect in this way; for, after repeated exsiccation, the solution remains clear and yellow: but here probably the fixed alkali takes the place of the volatile; for in larger quantities, and especially when the caustic vegetable alkali is made use of, the mixture smells of volatile alkali.

¹³³¹ Platina partly precipitated by neutral salts.

The volatile alkali, saturated with any acid, precipitates the platina in the same manner as the vegetable alkali in combination with acids: but these neutral salts precipitate only a determined quantity of platina; for after their effect has ceased, the liquor lets fall a pure calx of platina on the addition of vegetable or volatile alkali.

¹³³² Triple salts formed by this metal.

The calx of platina precipitated by mineral alkali, and then dissolved in any simple acid, shows nearly the same phenomena with volatile alkali as with the vegetable alkali. "Whence (says Mr Bergman) we may conclude, that platina dissolved in acids forms at first, both with the volatile and fixed vegetable alkali, a triple salt, difficult of solution, and which therefore almost always falls to the bottom unless the quantity of water be very large." Calcareous earth, whether aerated or caustic, produces the same phenomena as the mineral alkali, without any crystalline appearance.

¹³³³ Platina the most infusible substance in the world.

Platina has been remarkable ever since its first discovery for being the most infusible substance in the world. Messrs Macquer and Beaumé kept it in the most violent heat of a glass-house furnace for several days without perceiving any other alteration than that its grains adhered slightly to each other; but the adhesion was so slight that they separated even by touching. In these experiments the colour of the platina became brilliant by a white heat, but acquired a dull grey colour after it had been heated for a long time. They observed also, that its weight was constantly increased; which undoubtedly arose from the calcination of the iron it contained. Dr Lewis, after various attempts to fuse platina, found himself unable to succeed even in a fire which vitrified bits of glass-house pots and Hessian crucibles. Messrs Macquer and Beaumé first melted this refractory metal with a large burning-glass, 22 inches diameter and 28 inches focus. The power of this speculum was almost incredible, and far exceeded what is related of the lens of Tschirnhausen or the mirror of Villette. Its general

¹³³⁴ First melted by a burning mirror.

effects are related under the article *BURNING-Glass*. And as platina resisted this intense heat more than six times as long as the most unfusible substances formerly known, it appears to require a fire as many times stronger to melt it. It has been found, however, capable not only of fusion but of vitrification by the electric fire; and that it may also be melted by fire excited by dephlogisticated air: but M. de Lisle was the first who was able to melt it with the heat of a common forge when exposed to the blast of a double bellows in a double crucible. Thus its real specific gravity began first to be known. It must be observed, however, that this fusion was not performed on common platina, but on such as had been dissolved in aqua-regia and precipitated by means of sal ammoniac. M. Morveau repeated the experiment, and from 72 grains of platina obtained a regulus weighing $50\frac{1}{2}$; which seemed to have undergone a very imperfect fusion; for it did not adhere to the crucible or take its form, but seemed to be merely platina revived. Its specific gravity was also found to be no more than 10.045; but it was nearly as malleable as silver; and when it had been sufficiently hammered, its specific gravity was augmented to no less than 20.170, which is more than that of gold itself. M. Morveau found that he could melt the precipitate with different fluxes, such as a mixture of white glass, borax, and charcoal, and a mixture of white glass and neutral arsenical salt; and that the regulus thus obtained was more completely fused, but was not malleable, and obeyed the magnet; but the regulus obtained without addition did not show this mark of containing iron. He also found, that by means of the above mentioned flux of white glass, borax, and charcoal, he could melt crude platina. Since that time the fusion of platina has been accomplished by various chemists, and with different fluxes; and in proportion to the degree of purity to which the metal has been reduced, its specific gravity has also increased; so that it is now settled at 23, that of fine gold being 19.

¹³³⁵ Platina. May be vitrified by electric fire.

¹³³⁶ Its precipitate fusible in a common forge.

¹³³⁷ This precipitate, or even crude platina, fusible by the assistance of fluxes.

Though Dr Lewis could not accomplish the fusion of platina by the methods he attempted, he was nevertheless able to alloy it with other metals. Equal parts of gold and platina may be melted together by a violent fire, and the mixed metal formed into an ingot by pouring it into a mould. It is whitish, hard, and may be broken by a violent blow; but when carefully annealed, is capable of considerable extension under the hammer. Four parts of gold with one of platina form a compound much more fusible than the former, and likewise more malleable; so that it may be extended into very thin plates without being broken or even split at the edges. Dr Lewis remarks also, that though in this case it be alloyed with such a quantity of white metal, it nevertheless appears no paler than guineas usually are, which contain only one-twelfth of silver.

¹³³⁸ Alloyed by Dr Lewis with other metals.

¹³³⁹ With gold.

Equal parts of silver and platina melted together with a violent fire, form a much harder and darker-coloured mass than silver, which has also a large grain, though it preserves some ductility. Seven parts of silver with one of platina form a compound much more resembling silver than the other; but still coarser-grained and less white. From the experiments made on silver, however, it appears that no perfect union is

¹³⁴⁰ With silver.

Platina

formed betwixt the two; for after the mixture has been kept in fusion for a considerable time, most of the platina separates and falls to the bottom. Lewis observed, that silver melted with platina was thrown up with an explosion against the sides of the crucible.

Silver did not appear to be in any degree meliorated by its union with this metal, excepting by the superior hardness communicated to it; but copper seemed to be considerably improved. A large proportion of platina, indeed, as two-thirds or equal parts, produced an hard, brittle, and coarse-grained compound; but when a smaller quantity of platina is added, as from $\frac{1}{6}$ to $\frac{1}{12}$, or even less, a golden-coloured copper is produced, very malleable, harder, susceptible of a finer polish, smoother-grained, and much less subject to calcination and rust than pure copper.

1341
Copper considerably improved by union with platina.

1342
Unites most readily with zinc;

1343
And with the compound metals.

1344
The compound of brass and platina a proper material for speculums.

1345
Can scarce be united with mercury.

1346
Mercury leaves platina to unite with gold.

1347
May be united with forged and cast iron;

1348
And with tin, lead, or bismuth.

Of all metallic matters, however, zinc most readily unites with platina, and is most effectually dissolved by fusion. When the proportion of platina is considerable, the metal is of a bluish colour, the grain closer, without tarnishing or changing colour in the air, and they have not even the malleability of the semi-metal.

Platina unites readily with the compound metals, brass formed of copper and zinc, and bronze made of copper and tin. In the latter it was remarkable, that the compound metal took up more platina than both its ingredients separately can do. This compound was hard and capable of receiving a fine polish, but is subject to tarnish.

Equal parts of brass and platina formed a compound very hard, brittle, capable of receiving a fine polish, and not subject to tarnish. It is possible therefore that it might be used to advantage as a material for speculums; all materials for which, hitherto discovered, have the great inconvenience of tarnishing in the air, and that very quickly.

Platina amalgamates with mercury, but with much greater difficulty than gold, which will also separate the quicksilver after it has been united with the platina. The amalgamation of platina does not succeed but by very long trituration of the metals with water, as for instance a week; but if the trituration be performed with a mixed metal composed of gold and platina, the mercury seizes the gold, and leaves the platina untouched. Dr Lewis proposes this as a method of separating gold from platina; and it is that used in Peru, where gold and platina are sometimes naturally mixed in the ore; but we do not know whether this separation be quite complete.

Mr Morveau succeeded in uniting iron with platina, though Dr Lewis could not accomplish this. The latter succeeded, however, in uniting it with cast iron. The compound was much harder and less subject to rust than pure iron. It was also susceptible of a much finer polish.

Platina may be alloyed with tin, lead, or bismuth, but without any advantage. To lead and tin it gives the property of assuming blue, violet, or purple colours, by being exposed to the atmosphere.

Dr Lewis could not succeed in uniting platina with

arsenic; but M. Scheffer affirms, that if only one-twentieth of arsenic be added to platina when red hot in a crucible, the two substances will be perfectly fused and united into a brittle grey mass. This experiment did not succeed with Mr Margraaf; for he, having exposed to a violent fire during an hour a mixture of an ounce of platina with a fusible glass, composed of eight ounces of minium, two ounces of flints, and one ounce of white arsenic, obtained a regulus of platina well united and fused, weighing an ounce and 32 grains; the surface of which was smooth, white, and shining, and the internal parts grey; but which nevertheless appeared sufficiently white when filed. The experiment succeeded imperfectly also in the hands of Dr Lewis; but M. Fourcroy informs us, that "it has since been repeated, and that platina is in fact very fusible with arsenic, but that it remains brittle. In proportion as the arsenic is driven off by the continuance of the heat, the metal becomes more ductile; and by this process it is that M. Achard and M. de Morveau succeeded in making crucibles of platina by melting it a second time in moulds." (A)

M. Fourcroy seems to deny that platina can be united with mercury, contrary to what is mentioned above.—"Platina (says he) does not unite with mercury, though triturated for several hours with that metallic fluid. It is likewise known, that platina resists the mercury used in America to separate the gold. Many intermediaries, such as water, used by Lewis and Beaumé, and aqua-regia by Scheffer, have not been found to facilitate the union of these two metals. In this respect platina seems to resemble iron, to whose colour and hardness it likewise in some measure approaches." This last sentence, however, seems very little to agree with what he himself had before told us of M. Macquer's experiment of melting platina. "The melted portions (says he) were of a white brilliant colour, in the form of a button; they could be cut to pieces with a knife." This surely was a very small approach to the hardness of iron; and gives us an idea rather of the consistence of tin or lead. "One of these masses was flattened on the anvil, and converted into a thin plate without cracking or breaking, but it became hard under the hammer." In another experiment indeed the button of platina was brittle, and sufficiently hard to make deep traces in gold, copper, and even iron; but this was obtained from precipitated platina urged for 35 minutes by a strong blast furnace. In an experiment of this kind M. Beaumé even succeeded in melting the precipitate, along with certain fluxes, into a vitriform substance by two different processes. The precipitate of platina, mixed with calcined borax, and a very fusible white glass, was exposed, for 36 hours, in the hottest part of a potter's furnace; and afforded a greenish glass, inclining to yellow, without globules of reduced metal. This glass, treated a second time with cream of tartar, gypsum, and vegetable alkali, was completely melted, and exhibited globules of platina dispersed through its substance. M. Beaumé separated them by washing, and found them ductile. The same chemist afterwards, together

Platina.

1349
May be melted by means of arsenic.

1350
Fourcroy denies that platina can be united with mercury.

1351
Inconsistent in his account of its hardness.

1352
Precipitated platina vitrified by M. Beaumé.

Platina. together with M. Macquer, exposed precipitate of platina to the same burning mirror with which they had fused the metal: the precipitate exhaled a very thick and luminous fume, with a strong smell of aqua-regia: it lost its red colour, resumed that of platina, and melted into a perfect brilliant button, which was found to be an opaque vitreous substance, of an hyacinthine colour at its surface, and blackish within; and may be considered as a true glass of platina. It may however be observed, that the saline matters with which it was impregnated contributed doubtless to its vitrification.

1353 Precipitate by sal ammoniac fusible in a strong forge heat. "The orange-coloured precipitate obtained by pouring a solution of sal ammoniac into a solution of platina, appears to be a saline substance entirely soluble in water. This precipitate has a valuable property, discovered by M. de l'Isle, viz. that it is fusible without addition in a good furnace or common forge-heat. The platina melted by this process is a brilliant, dense, and close-grained button; but it is not malleable unless it has been exposed to a very strong heat. Macquer thinks that this fusion, like that of the grains of platina alone, exposed to the action of a violent fire, consists only in the agglutination of the softened particles; which being exceedingly more divided and minute than the grains of platina, adhere to and touch each other in a greater number of points than the grains; and in that manner render the texture of the metal much more dense, though no true fusion may have taken place. It seems, however, that if platina in grains be capable of fusion by the burning-glass, and of becoming considerably ductile, the precipitate of this metal formed by sal ammoniac may likewise be fused on account of its extreme division; and that its not being as ductile as the button of platina fused by the solar heat, may perhaps depend on its retaining a part of the matter it carried down with it in precipitation, of which it may be possible to deprive it by fire."

1354 This fusion supposed by Macquer not to be perfect. It being so extremely difficult to bring platina itself into fusion, one of the first attempts to purify it was by cupellation with lead. Thus the baser metals would be scorified; and, running through the crucible along with the lead, leave the platina in as great purity as though it had been melted by itself. This operation, however, was found almost equally difficult with the fusion of the metal by itself. Lewis failed in the experiment, though he applied the most violent heat of the ordinary cupelling furnaces. The vitrification and absorption of the lead indeed took place as usual; but in a short time the platina became fixed, and could not by any means be rendered fluid. Messrs Macquer and Beaumé succeeded by exposing an ounce of platina with two ounces of lead in the hottest part of a porcelain furnace, where the fire is continued for 50 hours without intermission. At the end of the operation the platina was flattened in the cupel; its upper surface was dull and rough, and easily separated; but its under surface was brilliant, and it was found easily to extend under the hammer; and on every chemical trial was found to be perfectly pure, without any mixture of lead. M. de Morveau likewise succeeded in cupelling a mixture of one drachm of platina and two drachms of lead in M. Macquer's wind-furnace. The operation lasted eleven or twelve hours, and a button

of platina was obtained which did not adhere to the cupel, was uniform, though rather rough, and of a colour resembling tin. It weighed exactly one drachm, and was not at all acted upon by the magnet. Thus it appears that platina may be obtained in plates or laminæ, which may be forged, and consequently may be employed in making very valuable utensils; and this the more especially as Mr Beaumé has observed that different pieces of it may be welded and forged like iron. After having heated two pieces of pure cupelled platina to whiteness, he placed them one upon the other, and striking them briskly with a hammer, found that they united together as quickly and firmly as two pieces of iron would have done.

The great specific gravity of platina has rendered it a very desirable matter for such as wish to adulterate the precious metal, and can procure the platina easily. This, however, can only be done in South America, where platina is met with in plenty. In Europe the scarcity of platina renders it a more valuable object than even the gold itself. Fears of this fraud, however, have undoubtedly given occasion to the prohibition of exporting it. There are great differences among chemists concerning the quantity of platina that can be mixed with gold without destroying the colour of the latter. Dr Lewis, as has already been observed, informs us, that four parts of platina may be mixed with one of gold, and yet the mixture be no paler than that for guineas; while Fourcroy asserts, that "it greatly alters the colour of the metal, unless its quantity be very small: thus, for example, a 47th part of platina, and all the proportions below that, do not greatly affect the colour of the gold." But whether this be the case or not, chemistry has afforded various ways of separating even the smallest proportion of platina from gold; so that there is now no reason to prohibit the importation of it to Europe, more than that of any other metal with which gold can be alloyed. The following are the methods by which the platina may be most readily discovered:

1356 Of the possibility of adulterating gold with platina. 1. By amalgamating the suspected metal with mercury, and grinding the mixture for a considerable time with water; by which the platina will be left, and the gold remain united with the quicksilver. 2. By dissolving a little of it in aqua regia, and precipitating with alkaline salt; the remaining liquor, in case the metal has been adulterated with platina, will be so yellow, that it is supposed a mixture of one thousandth part would thus be found out. 3. By precipitation with sal ammoniac, which throws down the platina but not the gold. If mineral alkali be used, the gold will be precipitated, but not the platina, unless the precipitant is in very large quantity. 4. By precipitation with green vitriol, which throws down the gold, and leaves the platina united with the menstruum.

All these methods, however, are not only attended with a considerable deal of trouble, but in some cases, for instance in suspected coin, it might not be eligible to use them. The hydrostatic balance alone affords a certain method of discovering mixtures of metals without hurting the texture of their parts. The great specific gravity of platina would very readily discover it if mixed with gold in any moderate quantity; and even in the smallest, the gravity of the mass could never be less than that of the purest gold: which circumstance

Manganese. circumstance alone, as gold is never worked without alloy, would be sufficient to create a just suspicion; after which some of the methods already mentioned might be tried. It is possible, however, that the hardness and ductility of platina might render it more proper for alloying gold than even copper or silver, usually made use of for this purpose.

§ 15. Of MANGANESE.

1359
New semi-metal afforded by manganese.

THIS substance is now discovered to afford a semi-metal different from all others, and likewise to possess some other properties of a very singular kind. Mr Scheele has investigated its nature with the utmost care; and the result of his inquiries are as follows:

1360
Properties of the common manganese treated with vitriolic acid.

1. Two drachms of levigated manganese, digested for several days in a diluted vitriolic acid, did not appear to be dissolved or diminished in quantity; nevertheless a yellowish white precipitate was procured by saturating the acid with fixed alkali. The remaining manganese was not acted upon by more of the same acid, but the addition of another half ounce nearly destroyed the acidity of the menstruum when boiled upon it.

2. With concentrated vitriolic acid an ounce of manganese was reduced to a mass like honey, and then exposed to the fire in a retort till it became red-hot. Some vitriolic acid came over into the receiver; and after breaking the retort, a mass was found in it weighing $12\frac{1}{2}$ drachms, hard and white in the inside, but red on the outside. A great part of it dissolved in distilled water, on the affusion of which at first it became very hot. The residuum after edulcoration weighed a drachm and an half, and was of a grey colour. Being calcined in a crucible with concentrated vitriolic acid till no more vapours arose, it was all dissolved by water excepting one drachm; which being again calcined with the same acid, an insoluble residuum of a white colour, and weighing only half a drachm, remained. This white residuum effervesced with borax, and melted into a transparent brown glass; it likewise effervesced with fixed alkali, changing into a brown mass, which yielded an hepatic smell with acids, and became at the same time gelatinous. The solution obtained by calcination was evaporated and set to crystallize. A few small crystals of selenite were first deposited, and afterwards some very fine large crystals of an oblique parallelopiped form, whose number increased as long as there was any liquid left. They tasted like Epsom salt, and Mr Westfeld supposes them to be alum; but according to Mr Scheele, they have no other resemblance to alum than that they contain the vitriolic acid.

1361

Entirely dissolved by phlogisticated vitriolic acid.

3. By phlogisticated vitriolic acid the manganese was entirely dissolved. To procure this acid in purity, Mr Scheele dipped some rags in a solution of alkali of tartar, and after saturating them with the fumes of burning brimstone, put them into a retort, pouring on them some dissolved acid of tartar, luting on a receiver which contained levigated manganese and water. After a warm digestion of only one day, the liquid of the receiver had become as clear as water, and a little fine powder, consisting principally of siliceous earth, fell to the bottom.

4. Two drachms of levigated manganese, digested

for several days with an ounce of pure colourless acid of nitre, did not appear to have deprived the menstruum of its acidity, or to have been affected by it in any degree. The liquor being distilled off, and the product of the distillation poured back on the residuum, a small quantity of it was dissolved. By a third distillation, and pouring back the liquor on the residuum, a complete solution was effected; and this quantity of acid appeared capable of dissolving nine drachms of the powder.

5. The solution of manganese thus saturated, was filtered and divided into two equal portions. Into one of these some drops of vitriolic acid were poured, by which a fine white powder was thrown down, which, however, did not settle to the bottom for some hours. It was soluble neither in boiling water nor in acids. The limpid solution, by evaporation, yielded some small crystals of selenite or gypsum.

6. From the other half of this solution, after evaporation by a gentle heat, about ten grains of small shining crystals of a bitter taste were obtained. On pouring some drops of vitriolic acid into the solution inspissated by a gentle heat, no precipitation, excepting of a little selenite, ensued; but as soon as it was inspissated to the consistence of honey, some fine acicular crystals, verging towards the same centre, began to form, but grew soft, and deliquesced in a few days after.

7. Phlogisticated nitrous acid dissolves manganese as readily as the phlogisticated vitriolic. A little levigated manganese mixed with some water was put into a large receiver, to which a tubulated retort was luted. Some ounces of common nitrous acid were put into the retort, to which some iron filings were added, taking care always to close the orifice with a glass stopple. The phlogisticated nitrous acid thus passed over into the receiver, and dissolved the manganese in a few hours: the solution was as limpid as water, excepting only a little fine siliceous earth. Another white precipitate, similar to that produced by adding vitriolic acid to the solution in pure nitrous acid, now began to fall; but in other respects this solution agreed with the former.

8. An ounce of purified muriatic acid was poured upon half an ounce of levigated manganese; which, after standing about an hour, assumed a dark brown colour. A portion of it was digested with heat in an open glass vessel, and smelled like warm aqua regia. In a quarter of an hour the smell was gone, and the solution became clear and colourless. The rest of the brown solution being digested, to see whether the muriatic acid would be saturated with manganese, an effervescence ensued, with a strong smell of aqua regia, which lasted till next day, when the solution was found to be saturated. Another ounce of acid was poured upon the residuum, which was followed by the same phenomenon, and the manganese was entirely dissolved, a small quantity of siliceous earth only remaining. The solution, which was yellow, being now divided into two portions, some drops of vitriolic acid were poured into the one, by which it instantly became white, and a fine powder, insoluble in water, was precipitated. Some small crystals of selenite were formed by evaporation, and the residuum exhibited the same phenomenon with those above mentioned with nitrous

1362

Precipitate and crystals obtained from the solution.

1363

Manganese dissolved by phlogisticated nitrous acid.

1364

Effects of it on spirit of salt.

1365

Entirely dissolved by this acid.

Manganese trous acid. By evaporating the other half, some small shining angular crystals were obtained, similar to those procured by means of the nitrous acid.

¹³⁶⁶ 9. Very little manganese was dissolved by fluor acid, even after several days digestion. A great quantity was required to form a saturated solution. It had very little taste, and gave a small quantity of precipitate with fixed alkali. But if a neutral salt, composed of fluor acid and sal ammoniac, be added, a double decomposition takes place, and the manganese is precipitated along with the fluor acid.

¹³⁶⁷ 10. A drachm of phosphoric acid digested with as much powdered manganese, dissolved but little of it; and, though evaporated to dryness, the residuum tasted very acid; but by adding more manganese the acid was at last saturated. On adding microcosmic salt to a solution of manganese, a decomposition takes place similar to that effected by the combination of fluor acid and volatile alkali.

¹³⁶⁸ 11. Pure acid of tartar dissolved manganese partly in the cold, and more effectually by means of heat. The whole, however, could not be dissolved, though the acid was at last saturated by adding a great quantity of the mineral. On adding a solution of soluble tartar, a double decomposition took place.

¹³⁶⁹ 12. Little was dissolved by distilled vinegar, though boiled on manganese; but after distilling spirit of verdigris several times upon it, the acid at last became saturated. The solution, evaporated to dryness, left a deliquescent mass. Little or none of the remaining manganese was dissolved by concentrated vinegar, though repeatedly distilled upon it.

¹³⁷⁰ 13. With acid of lemons the whole was dissolved with effervescence, excepting only some white earth.

¹³⁷¹ 14. Water impregnated with fixed air likewise dissolved manganese, but parted with it on the addition of alkali, or spontaneously by exposure to the air.

From these experiments Mr Scheele concludes, that manganese has a strong elective attraction for all phlogistic substances; and that this attraction becomes stronger, if there be present a menstruum which can unite with the phlogisticated manganese. Thus it attracts phlogiston more powerfully than even the nitrous acid itself in the moist way. By saturation with phlogiston, manganese has the property of losing its black colour, and assuming a white one, which is unusual, the phlogiston generally communicating a black or dark colour to the substances with which it was united.

¹³⁷² That manganese naturally contains some phlogiston, though but in small quantity, appears from evaporating a solution of it in vitriolic acid to dryness, and then distilling the mass in a glass retort in an open fire. When the retort begins to melt, the acid parts fly off from the manganese in a sulphureous state, leaving the former of its natural black colour. By distilling the mass remaining after evaporation of the nitrous solution, a green volatile nitrous acid remains, and the black calx of manganese remains as before. A solution of this mineral in vitriolic or nitrous acid, precipitated by fixed alkali, retains its colour; but when calcined in the open fire, again becomes black.

¹³⁷⁵ By losing its phlogiston, manganese becomes insoluble in pure acids; and therefore the residuum of the

above mentioned distillations cannot be dissolved by adding more of the vitriolic or nitrous acids: but if that which has come over into the receiver be poured back into the retort, a solution will again take place by reason of the manganese resuming the phlogiston it had parted with to the acid.

On this principle our author explains the reason of the partial solutions of this mineral above mentioned. Part of it is dissolved, for instance in the vitriolic acid, while the remainder is found insoluble. This happens (says he), "because the undissolved portion has parted with the little phlogiston it naturally possessed to that portion of manganese which is taken up by the vitriolic acid during the first digestion; for without that principle it is insoluble."

Manganese attracts phlogiston more strongly when combined with some acid than by itself, as appears from the following experiments.

¹³⁷⁷ 1. Levigated manganese, digested or boiled with a solution of sugar, honey, gum Arabic, hartshorn, jelly, &c. remains unchanged; but on mixing the pounded mineral with diluted vitriolic, or pure nitrous acid, and then adding some of these substances, the whole is dissolved, the black colour vanishes by degrees, and the solution becomes as limpid as water. So strong is the attraction of manganese for phlogiston in these circumstances, that metals, the noble ones not excepted, render it soluble in these acids in a limpid form.

¹³⁷⁸ Concentrated vitriolic acid, indeed, dissolves manganese entirely without any phlogiston. "It would be difficult (says Mr Scheele) to comprehend whence the phlogiston in this case should come, if we were not certain that several substances, which have a great attraction for phlogiston, can attract it in a red heat. Quicksilver and silver, when dissolved in the purest nitrous acid, really lose their phlogiston, which is a constituent part of these metals. This appears from the red vapours in which the acid arises; and the dissolved metallic earth cannot be again reduced to its metallic form, till it has acquired the lost phlogiston, which is effected either by precipitation with complete metals or by heat alone. Thus manganese can attract the quantity of phlogiston necessary for its solution by means of concentrated vitriolic acid from heat. It is not probable that the concentrated acid undergoes a decomposition in this degree of fire; for if you saturate half an ounce of this acid with alkali of tartar, and afterwards calcine in a retort, with a receiver applied, an ounce and a half of powdered manganese, with an equal quantity of the same vitriolic acid, then dissolve the calcined mass in distilled water, and likewise wash well the receiver, which contains some drops of vitriolic acid, which are also to be added to the solution, and lastly add the same quantity of alkali, there will be no mark of superabundant acid or alkali. Thence it may be concluded, that the phlogiston in the vitriolic acid, if there really exists any in it, contributes nothing to the solution. But the manganese precipitated by alkali contains a considerable quantity of it; in consequence of which it is afterwards entirely soluble in acids without any addition.

¹³⁷⁹ "The effects of volatile sulphureous acid on manganese, clearly prove what has been asserted. The manganese attracts the phlogiston contained in this acid, which is the cause of its great volatility, and which renders

Manganese.

Partial solutions of manganese explained on this principle.

Strong attraction of manganese when combined with acids for phlogiston.

Why the concentrated acid of vitriol dissolves manganese without addition.

Why the volatile sulphureous acid dissolves it.

Manganese. renders the former soluble in the new pure vitriolic acid. If this solution be mixed with concentrated vitriolic acid and distilled, no volatile sulphureous acid is obtained; and if it be precipitated by means of fixed vegetable alkali, vitriolated tartar is obtained; which proves that manganese has a stronger attraction than vitriolic acid for phlogiston in the moist way.

1380
Effects of
nitrous acid
on manga-
nese ex-
plained.

"The effects of nitrous acid on this substance are similar to those of vitriolic acid. Could spirit of nitre sustain as great a degree of heat as the concentrated vitriolic acid, it would also entirely dissolve the manganese by means of the phlogiston attracted by heat; but as this is not the case, it is necessary to add phlogiston in the manner above mentioned. The manganese decomposes phlogisticated nitrous acid, for the same reason that it does the volatile sulphureous acid; and that the phlogiston of this acid really combines with the manganese, is manifest from this, that the affusion of vegetable acid produces no smell of aqua fortis by displacing the phlogisticated acid of nitre. By distillation with pure vitriolic acid also, the nitrous acid is expelled, not in a smoking state, and of a yellow colour, but pure and colourless.

"In the solution of manganese by means of gum arabic or sugar, a very considerable effervescence takes place, owing to the extrication, or probably rather the production, of fixed air from the mixture; but with phlogisticated acid of nitre no such phenomenon takes place, because the manganese is combined with pure phlogiston; and if this should be again separated, there is no cause for the production of fixed air. This mineral is also dissolved without effervescence, by uniting it with nitrous acid and metals, arsenic or oil of turpentine."

1381
Existence of
phlogiston
in the mu-
riatic acid
proved.

As muriatic acid dissolves manganese without addition, Mr Scheele is of opinion that this proves the existence of phlogiston in that acid, as has already been taken notice of. The manganese digested in the cold with spirit of salt assumes a dark brown colour; for it is a property of this substance that it cannot be dissolved into a colourless liquor without phlogiston, but has always a red or blue colour; but with spirit of salt the solution is more brown than red, on account of the fine particles of the manganese floating in the liquid. Here the mineral adheres but loosely to the acid, so that it may be precipitated by water.

1382
Explana-
tion of the
action of
acid of tar-
tar and
acid of le-
mons.

The effects of acid of tartar and acid of lemons upon manganese are likewise explained on the principle already laid down, viz. the extreme attraction this substance has for phlogiston. Thus it attracts part of that naturally contained in these acids, decomposing one part of them, and being dissolved by the other. This destruction of the acid is similar to that of the sugar, gum arabic, &c. which render it soluble in nitrous acid; for if a proper quantity of these are added, the manganese will be dissolved, without a possibility of recovering the smallest particle of the vegetable substances employed; and if the solution be slowly evaporated and calcined, there will not remain the smallest mark of burned sugar or gum. During this decomposition, a pungent vapour arises, which, being collected, appears to be true vinegar. It is obtained in its purest state from diluted vitriolic acid, sugar, and manganese.

1383
Of fluor
acid.

Fluor acid dissolves but very little manganese, owing to its precipitating a salt which envelopes the particles

N 74.

of manganese, and prevents the further action of the menstruum. In all precipitations of manganese, however, by means of mild fixed alkalies, the full quantity is not procured; because the fixed air, detached from the mineral, dissolves part of it.

Though manganese decomposes nitre, yet this does not happen till the mixture becomes red-hot. If phlogisticated manganese be mixed with an equal quantity of nitre, and distilled in a glass retort, the mixture begins to grow black before the retort becomes red-hot, but no nitrous acid goes over. By lixiviation, no mark of uncombined alkali is met with; but phlogisticated nitrous acid is extricated by the application of tamarinds, or any vegetable acid. Three parts of phlogisticated manganese, mixed with one part of finely pounded nitre, yields no nitrous acid, though the nitre is alkalized as soon as the mixture becomes black in the retort.

Mr Scheele proceeds now to another set of experiments upon manganese united with phlogiston. In order to procure it in this state, the best method is to dissolve in distilled water, and crystallize the salt obtained by solution of manganese in vitriolic acid, and then precipitate it with vegetable fixed alkali. In this state it is white like chalk; but by calcination in an open fire, the superfluous phlogiston flies off, and the calx regains its usual black colour. This change of colour likewise happens when the precipitation is made with caustic alkalies, whether fixed or volatile. The precipitate, indeed, in this case, is white when kept close from the air, but assumes a brown colour when exposed to it for any time: But when the precipitation is made by mild alkali, the white colour is preserved by the fixed air, which in this case it also contains. By diluting the solution with a considerable quantity of water, and precipitating with caustic alkali, the precipitate is brown from the very beginning, owing to the air in the liquid attracting the phlogiston from the manganese. The precipitate formed by lime-water is also brown; but on adding more of a strong solution of manganese, and afterwards precipitating with caustic alkali, the powder falls of a white colour; because the air, being already saturated with phlogiston, cannot take up any more. The results of Mr Scheele's experiments on this phlogisticated manganese are,

1. An ounce of this substance distilled by itself in a glass retort, with a strong fire, yielded a great quantity of fixed air with some drops of water. The residuum poured warm out of the retort grew red-hot, and set the paper on fire.

2. On repeating the experiment with only a drachm of phlogisticated manganese, and tying a bladder to the neck of the retort, three ounce-measures of air came over: the residuum was of a light grey colour; dissolved in acids without addition of any more phlogiston; and took fire in that degree of heat in which sulphur smokes, but does not burn. From these experiments, says Mr Scheele, it is evident, that phlogiston does not separate from manganese if the access of air be prevented.

3. One part of finely powdered manganese boiled in four of oil-olive, effervesced violently, and dissolved into a kind of salve.

4. On distilling a mixture of finely powdered manganese and charcoal, with an empty bladder tied to the mouth of the retort, a quantity of fixed air was extricated

cated when the retort began to melt and distended the bladder. The residuum was mostly soluble in diluted vitriolic acid.

5. On distilling half an ounce of powdered manganese with two drachms of sulphur, the latter partly rose into the neck of the retort, and some volatile acid vapours penetrated through the lute. The distillation was continued till the retort began to melt; and, on cooling, the residuum was found to weigh $5\frac{1}{2}$ drachms. It was of a yellowish-grey colour; and dissolved in spirit of vitriol with effervescence, yielded an hepatic smell, some sulphur being also precipitated at the same time. By calcination in the open air, the sulphur was dissipated; but great part of the mass was rendered soluble on account of its having been penetrated by the acid vapour, and shot into crystals as though it had been formally dissolved in volatile sulphureous acid; and by repeating the calcination with more sulphur, the whole became at last entirely soluble, and was reduced to crystals.

1390
By calcina-
tion with
nitre.

Finely powdered manganese, triturated with nitre, and strongly calcined in a crucible, unites with the alkali of the nitre, while the acid is dissipated in the air. The mass formed by the union of the manganese and alkali is of a dark green colour, and soluble in water, communicating also a green colour to the liquid; but in a short time a fine yellow powder (an ochre of iron) falls to the bottom, leaving the liquor of a blue colour. By the addition of water, this solution first assumes a violet colour, grows afterwards red, and a precipitation of the manganese takes place, which resumes its natural colour as soon as it has fallen. The same precipitation takes place on the addition of a few drops of acid, or by exposure for some days to the open air. As for the dark red colour assumed by the solution when the precipitate is about to fall, Mr Scheele conjectures that the particles of manganese may naturally have a red colour, which becomes visible when the substance is dispersed through a menstruum without being perfectly dissolved.

1391
With the
addition of
arsenic.

7. By the addition of finely powdered white arsenic to the alkaline mass of nitre and manganese, the green colour disappears, and the whole becomes white; phlogisticated manganese being also precipitated on the addition of water. This arises from the more powerful attraction of manganese for the phlogiston of the arsenic than that of the arsenical acid itself; and for the same reason, if the mass be calcined with charcoal, or any other phlogistic substance, a colourless solution will be obtained.

1392
By distilla-
tion with
sal ammo-
niac.

8. Half an ounce of phlogisticated manganese, distilled in a retort with an equal quantity of powdered sal ammoniac, yielded first a concrete volatile salt, after which some sal ammoniac undecomposed arose in the neck of the retort. Half an ounce of pure dephlogisticated manganese, mixed with two drachms of powdered sal ammoniac, yielded alkali in its caustic state. Both residuums were soluble in water; which shows that manganese attracts phlogiston from the volatile alkali.

1393
By distilla-
tion with
pure ni-
trous acid.

9. On digesting finely powdered manganese for some weeks with pure nitrous acid and some volatile alkali, a great number of air-bubbles rise to the top, and the volatile alkali is entirely decomposed; for though the

Vol. IV. Part II.

mixture be afterwards distilled in a retort with the addition of quicklime, not the least urinous smell can be perceived. This decomposition is effected by the manganese attracting the phlogiston of the volatile alkali; for that the nitrous acid has no share in this, is proved by the following experiment.

10. An ounce of well triturated manganese was distilled with half an ounce of sal ammoniac; and a li- quid alkali, such as that obtained from sal ammoniac and quicklime, was procured. On repeating this experiment, with the variation only of a bladder instead of a receiver, the same kind of air was obtained as that which rises to the top of the nitrous mixture. Though the emission of this air indicated a destruction of the volatile alkali, our author explains the reason of its being still obtained in a caustic state by the phlogiston taken from the alkali being more than sufficient to render the alkali soluble in muriatic acid; in consequence of which, the superfluous quantity combines with the manganese, and enables it to decompose the sal ammoniac in the ordinary way. It must be owned, however, that his reasoning on this subject is not entirely satisfactory, nor does the account he gives of his experiments seem entirely consistent with itself. See *Scheele's Chem. Essays*, Essay V. § xxxix.

11. Powdered manganese, distilled with an equal quantity of white arsenic, underwent no change, the arsenic flying off in its proper form; but with an equal quantity of yellow orpiment, some volatile sulphureous acid came over first, then a yellow sublimate, and at last a little red sublimate arose. On augmenting the fire by degrees, the orpiment remained obstinately attached to it. Similar effects ensued on treating manganese with an equal quantity of antimony; which likewise yielded a pungent sulphureous acid, but no sublimate. By calcination in the open air these compounds are decomposed; and the manganese, united with vitriolic acid, becomes soluble in water.

12. On distilling manganese with an equal quantity of finely pounded cinnabar, a volatile sulphureous acid came over first; then a little cinnabar was sublimed into the neck of the retort; and at last the quicksilver, which had been the basis of the cinnabar, began to distil: the residuum, being a combination of manganese and sulphur, was similar to the compounds already described.

13. With an equal quantity of corrosive sublimate, manganese underwent no change; but when sublimed with an equal quantity of mercurius dulcis, a corrosive sublimate, and then mercurius dulcis, arose into the neck of the retort. The reason of this is, that the mercurius dulcis contains a portion of phlogiston; by being deprived of which it ceases to be mercurius dulcis, and becomes corrosive sublimate: but by reason of the strong attraction of manganese for phlogiston, the mercurius dulcis parts with that portion which is necessary to keep it in its mild state, and thus is converted into corrosive mercury.

SECT. IV. *Inflammable Substances.*

THESE may be divided into the following classes: 1. Sulphurs. 2. Ardent spirits. 3. Oils and fats. 4. Resins. 5. Bitumens; and, 6. Charcoal.

Sulphur.

§ 1. SULPHURS.

1399
Sulphur.

1. *Common sulphur.* For the extraction of this substance from its ores, see SULPHUR. The artificial composition of it we have already related, n° 715; and have now only to take notice of a very few of its properties, which come more properly under this section.

1400
Crystalliza-
tion.

Sulphur, as commonly used in commerce and the arts, is of a pale yellow colour, of a disagreeable and peculiar smell, which is rendered more sensible when it is heated or rubbed. By rubbing, it receives very curious electrical qualities: (See ELECTRICITY.) Its specific gravity is considerably greater than that of water, though less than earths or stones. In close vessels, sulphur is incapable of receiving any alteration. It melts with a very gentle heat; and then is sublimed, adhering to the capital in small, very fine, needle-like crystals, called *flowers of sulphur*. It may thus be sublimed many times without alteration. If sulphur is exposed to a heat barely sufficient to melt it, and very slowly cooled, it crystallizes in form of many needles crossing one another. Some of these pointed crystals may also be observed in the interior parts of the lumps of sulphur which have been melted, and cast into cylindrical moulds, as they are commonly sold; because the centre of these cylindrical rolls is more slowly cooled than the surface. Sulphur also gives this needle-like form to cinnabar, antimony, and many other minerals containing it. Sulphur may be decomposed in several ways. The most simple is by burning; which we have already taken notice of, n° 623. It may also be very effectually decomposed by mixing it with iron filings and water. In this case the phlogiston is dissipated, and the acid uniting with the iron forms a green vitriol.

1401
Decompo-
sed by a
superabun-
dant of
phlogiston.

It is very remarkable, that though sulphur is composed of vitriolic acid and phlogiston, yet the addition of more inflammable matter, so far from making the union stronger, weakens it to a great degree: and hence we have another method of decomposing this substance; namely, by combining it with a large quantity of oil, and distilling the compound.

Sulphur is capable of being easily dissolved in expressed oils, but very difficultly in essential ones. These compositions are called *balsams of sulphur*; and are sometimes employed in medicine, but are found to be of a very heating nature. They are much used by farriers. According to Mr Beaumé, sulphur cannot be dissolved in oil, without a heat sufficient to melt it. A larger quantity is kept dissolved when the mixture is hot, than when cold; and consequently the sulphur, especially if it has been dissolved in a thin essential oil, crystallizes on cooling the mixture. The sulphur, thus separated from the oil, is found not to be altered in any respect from what it formerly was; but if the mixture is exposed to a degree of heat capable of entirely decomposing the oil, the sulphur is decomposed along with it, and the same products are obtained by distilling this mixture to dryness, as if a mixture of pure oil of vitriol and oil were distilled. These products are, first a portion of oil, when an essential oil was made use of in the composition of the balsam; then some volatile sulphureous acid, which is at first

watery, and afterwards becomes stronger; along with this acid more oil arises, which becomes more and more thick towards the end of the distillation; and lastly, when the retort has been made red hot, nothing remains but a fixed coal.

In this process we find, that both the sulphur and oil are decomposed. The acid of the sulphur seems to attack the watery principle of the oil, while its phlogiston remains confounded with that of the oil, or is dissipated in vapours. Hence, though the vitriolic acid in sulphur is concentrated to the utmost degree, and perfectly free from water, what rises in this distillation is very aqueous, by reason of the water which it attracts from the oil.

Spirit of wine does not sensibly act upon sulphur in its liquid state; but if both the spirit of wine and sulphur meet in the state of vapour, they will then unite, and a perfect solution will take place. By methods of this kind, many combinations might be effected, which have been hitherto thought impossible.

1402
How solu-
ble in spirit
of wine.

Pure sulphur unites easily with all metals; gold, platina, and zinc, excepted. The compounds, except that with mercury, possess a metallic lustre without any ductility. The sulphur may be separated by exposing the mixture to a strong fire, (see METALLURGY,) or by dissolving the metalline part in acids. The sulphur, however, defends several of the metals from the action of acids; so that this dissolution succeeds but imperfectly. The reguline part of antimony is more easily separated from sulphur by means of acids than any other metalline substance. Alkaline salts will separate the sulphur from all metals in fusion, but they unite with it themselves, and form a compound equally capable of dissolving the metal.

1403
Its union
with me-
tals.

Sulphur united with quicksilver forms the beautiful pigment called *cinnabar*, or *vermilion*; which is so much used in painting, that the making of it is become a distinct trade. Neuman relates, that in the making of cinnabar by the Dutch method, six or eight parts of quicksilver are made use of to one of sulphur. The sulphur is first melted, and then the quicksilver is stirred into it; upon which they unite into a black mass. In this part of the process the mixture is very apt to take fire; of which it gives notice by swelling up to a great degree. The vessel must then be immediately covered. The mass being beaten to powder, is afterwards to be sublimed in large earthen jars almost of an equal wideness from end to end; these are hung in a furnace by a strong rim of iron. When the matter is put in, the mouth of the vessel is covered, the fire increased by degrees, and continued for several hours, till all the cinnabar has sublimed; care being taken to introduce at times an iron rod to keep the middle clear; otherwise the cinnabar concreting there, and stopping up the passage, would infallibly burst the vessels.

1404
Vermilion.

The quantity of sulphur directed in the common receipts for making cinnabar is greatly larger than the above; being no less than one-third of the quantity of quicksilver employed: accordingly it has been found, that the sublimate, with such a large quantity of sulphur, turned out of a blackish colour, and required to be several times sublimed before it became perfectly red; but we cannot help thinking, that by one gentle sublimation

Sulphur. sublimation the superfluous sulphur might be separated, and the cinnabar become perfectly pure the second time. Hoffman gives a curious method of making cinnabar without sublimation: by shaking or digesting a little mercury with volatile tincture of sulphur, the mercury readily imbibes the sulphur from the volatile spirit, and forms with it a deep red powder, not inferior in colour to the cinnabar prepared in the common manner. Dr Lewis has found the common solutions of sulphur by alkalies, or quicklime, to have a similar effect. This cinnabar will likewise be of a darker or lighter colour, according as the solution contains more or less sulphur.

1405
Pulvis fulminans.

Sulphur is a principal ingredient in gun-powder, (see GUN-POWDER.) It also enters the composition of the *pulvis fulminans*. This consists of three parts of nitre, two of the dry alkali of tartar, and one part of sulphur, well ground together. If a little quantity of this powder is laid on an iron-spoon or shovel, and slowly heated, it will explode, when it arrives at a certain degree of heat, with astonishing violence and noise. The most probable opinion concerning this is, that the fixed air contained in the alkali is, by the acid vapours acting upon and endeavouring to expel it all at once, driven off with such force, that a loud explosion is produced.

1406
Phosphorus of urine.

2. *Phosphorus of Urine*. This is a very inflammable substance, composed of phlogiston united with a certain acid, the properties of which we have already taken notice of, n° 904 *et seq.* The preparation of it was long a secret, and only perfectly discovered by Mr Margraaff, who published it in the Berlin Memoirs in 1743. This process being by far the best and most practicable, we shall content ourselves with inserting it alone.

1407
Mr Margraaff's process for making.

Two pounds of sal ammoniac are to be accurately mixed with four pounds of minium, and the mixture distilled in a glass retort; by which means a very penetrating, caustic alkaline spirit will be obtained. The residuum, after the distillation, is a kind of *plumbum corneum*; n° 812. This is to be mixed with nine or ten pounds of extract of urine, evaporated to the consistence of honey. (Seventy or eighty gallons of urine are required to produce this quantity of extract.) The mixture is to be made slowly in an iron pot set over the fire, and the matter frequently stirred. Half a pound of powdered charcoal is then to be added, and the evaporation continued till the whole is reduced to a black powder. This powder is to be put into a retort, and urged with a graduated heat, till it becomes red hot, in order to expel all the volatile alkali, fetid oil, and ammoniacal salt, that may be contained in the mixture. After the distillation, a black friable residuum remains, from which the phosphorus is to be extracted by a second distillation and a stronger heat. Before it is subjected to another distillation, it may be tried by throwing some of it upon hot coals. If the matter has been well prepared, a smell of garlic exhales from it, and a blue phosphorical flame is seen undulating along the surface of the coals.

The matter is to be put into a good earthen retort, capable of sustaining a violent fire. Three quarters of the retort are to be filled with the matter which is to yield the phosphorus, and it is to be placed in a furnace capable of giving a strong heat. Mr Margraaff

divides the matter among six retorts, so that if any accident happens to one, the whole matter is not lost. The retorts ought to be well luted to a receiver of a moderate size, pierced with a small hole, and half full of water; and a small wall of bricks must be raised between the furnace and receiver, in order to guard this vessel against heat as much as possible. The retorts are to be heated by slow degrees for an hour and an half; then the heat is to be increased till the vessels are red hot, when the phosphorus ascends in luminous vapours. When the retort is heated till between a red and white, the phosphorus passes in drops, which fall and congeal in the water at the bottom of the receiver. This degree of heat is to be continued till no more comes over. When a retort contains eight pints or more, this operation continues about five hours.

In the first distillation, phosphorus never passes pure, but is always of a blackish colour, by reason of its carrying along with it some part of the coal. From this, however, it may be purified by rectification in a small glass-retort, to which is luted a receiver half full of water. A very gentle heat is sufficient; because phosphorus, once formed, is very volatile; and as the fuliginous matter was raised probably by the fixed air emitted by the charcoal in the instant of its union with the phosphorine acid, none of it can arise in a second distillation.

The phosphorus is then to be divided into small cylindrical rolls, which is done by putting it in glass-tubes immersed in warm water; for the phosphorus is almost as fusible as suet. It takes the form of the glass-tubes; from which it may be taken out, when it is cold and hardened. This must be done under water, lest the phosphorus should take fire.

This concrete continually appears luminous in a dark place; and by a very slight heat takes fire, and burns far more vehemently than any other known substance. Hence it is necessary to be very cautious in the distillation of it; for if the receiver should happen to break while the phosphorus is distilling, and a little flaming phosphorus fall upon the operator's legs or hands, it would burn its way to the bone in less than three minutes. In this case, according to Mr Hellot, nothing but urine will stop its progress.

Though phosphorus takes fire very readily by itself, it does not inflame at all by grinding it with other inflammable bodies, as camphor, gun-powder, or essential oils. In grinding it with nitre, some luminous flashes are observed; but the mixture never burns, unless the quantity of phosphorus be large in proportion to the nitre: rubbed pretty hard on a piece of paper or linen, it sets them on fire if they are rough, but not if they are smooth. It fires written paper more readily than such as is white, probably from the former having more asperities. On grinding with iron-filings, it presently takes fire.

Oils ground with phosphorus appear, like itself, luminous in a temperately warm place; and thus become a liquid phosphorus, which may be rubbed on the hands, &c. without danger. Liquid phosphorus is commonly prepared by grinding a little of the solid phosphorus with oil of cloves, or rubbing it first with camphor, and this mixture with the oil. A luminous *amalgam*, as it is called, may be obtained, by digesting

Sulphur.

1403

Redification of phosphorus.

1409

Process sometimes dangerous.

1410

Liquid phosphorus.

Sulphur. a scruple of solid phosphorus with half an ounce of oil of lavender, and, when the phosphorus begins to dissolve and the liquor to boil, adding a drachm of pure quicksilver; then briskly shaking the glass for five or six minutes till they unite.

1411
Experiments on phosphorus with spirit of wine.

Rectified spirit of wine, digested on phosphorus, extracts a part of it, so as to emit luminous flashes on being dropt into water. It is computed that one part of phosphorus will communicate this property to 600,000 parts of spirit. The liquor is never observed to become luminous of itself, nor in any other circumstance except that above mentioned. By digestion for some months, the undissolved phosphorus is reduced to a transparent oil, which neither emits light nor concretes in the cold. By washing with water, it is in some measure revived; acquiring a thicker consistence, and becoming again luminous, though in a less degree than at first. During this digestion, the glass is very apt to burst.

1412
With essential oils and acids.

Phosphorus is partially dissolved by expressed oils; and totally, or almost so, in essential oils and ether. When essential oils are saturated with it by heat, a part of the phosphorus separates, on standing in the cold, in a crystalline form. Concentrated spirit of salt has no action on it. In distillation, the spirit rises first, and the phosphorus after it unchanged. Spirit of nitre dissolves it, and the dissolution is attended with great heat and copious red fumes; so that great part of the spirit distils without the application of any external heat, and the phosphorus at last takes fire, explodes, and bursts the vessels. Oil of vitriol likewise dissolves phosphorus, but not without a heat sufficient to make the acid distil. The distilled liquor is white, thick, and turbid; the residuum is a whitish tenacious mass, which deliquesces, but not totally, in the air. Phosphorus itself is resolved into an acid liquor on being exposed two or three weeks to the air, its inflammable principle seeming by degrees to be dissipated.

Phosphorus has been reported to produce extraordinary effects in the resolution of metallic bodies: but from the experiments that have been made with this view, it does not appear to have any remarkable action on them; at least on the precious ones, gold and silver, for the resolution or subtilization of which it has been chiefly recommended. The following experiments were made by Mr Margraaff.

1413
Mr Margraaff's experiments with metals.

1. A scruple of filings of gold were digested with a drachm of phosphorus for a month, and then committed to distillation. Part of the phosphorus arose, and part remained above the gold, in appearance resembling glass: this grew moist on the admission of air, and dissolved in water, leaving the gold unaltered. Half a drachm of fine silver, precipitated by copper, being digested with a drachm of phosphorus for three hours, and the fire then increased to distillation, greatest part of the phosphorus arose pure, and the silver remained unchanged. Copper filings being treated in the same manner, and with the same quantity of phosphorus, the phosphorus sublimed as before; but the remaining copper was found to have lost its metallic brightness, and to take fire on the contact of flame. Iron filings suffered no change. Tin filings run into granules, which appeared to be perfect tin. Filings of lead did the same. The red calx of mercury, called

precipitate per se, treated in the same manner, was totally converted into running quicksilver. 2. Regulus of antimony suffered no change itself, but occasioned a change in the consistence of the phosphorus; which, after being distilled from this semimetal, refused to congeal, and continued, under water, fluid like oil-olive. With bismuth there was no alteration. A drachm of phosphorus being distilled and cohobated with an equal quantity of zinc, greatest part of the zinc sublimed in form of very light pointed flowers of a reddish-yellow colour: these flowers, injected into a red-hot crucible, took fire, and run into a glass resembling that of borax. White arsenic, sublimed with phosphorus, arose along with it in form of a mixed red sublimate. Sulphur readily unites with phosphorus into a mass which smells like *hepar sulphuris*. This does not easily take fire on being rubbed; but exposed to a moderate dry heat, it flames violently, and emits a strong sulphureous fume. If phosphorus is burnt in an open vessel, a quantity of acid remains behind; and if a glass bell is held over it, an acid likewise sublimes in the form of white flowers.

3. *Mr Canton's phosphorus.* This is a composition of quicklime and common sulphur. The receipt for making it is as follows. "Calcine some common oyster-shells, by keeping them in a good coal-fire for half an hour; let the purest part of the calx be pulverized and sifted. Mix with three parts of this powder one part of flowers of sulphur. Let this mixture be rammed into a crucible of about an inch and a half in depth till it be almost full; and let it be placed in the middle of the fire, where it must be kept red hot for an hour at least, and then set by to cool: when cold, turn it out of the crucible; and cutting or breaking it to pieces, scrape off, upon trial, the brightest parts; which, if good phosphorus, will be a white powder. This kind of phosphorus shines on being exposed to the light of the sun, or on receiving an electrical stroke.

1414
Mr Canton's phosphorus.

4. *Phosphorus of Homberg.* This substance, which has the singular property of kindling spontaneously when exposed to the air, was accidentally discovered by Mr Homberg, as he was endeavouring to distil a clear flavourless oil from human excrements. Having mixed the excrement with alum, and distilled over as much as he could with a red heat, he was much surprised at seeing the matters left in the retort take fire upon being exposed to the air, some days after the distillation was over. This induced him to repeat the operation, in which he met with the same success; and he then published a process, wherein he recommended alum and human excrement for the preparation of the phosphorus. Since his time, however, the process has been much improved; and it is discovered, that almost every vitriolic salt may be substituted for the alum, and most other inflammable substances for the excrement; but though alum is not absolutely necessary for the success, it is one of the vitriolic salts that succeed best. The following process is recommended in the Chemical Dictionary.

1415
Homberg's phosphorus or pyrophorus.

Let three parts of alum and one of sugar be mixed together. This mixture must be dried in an iron shovel, over a moderate fire, till it be almost reduced to a blackish powder or coal; during which time it must be stirred with an iron spatula. Any large masses must be

1416
Best method of preparing.

¹⁴¹⁷ Sulphur. be bruised into powder; and then it must be put into a glass matrafs, the mouth of which is rather strait than wide, and seven or eight inches long. This matrafs is to be placed in a crucible, or other earthen vessel, large enough to contain the belly of the matrafs, with about a space equal to that of a finger all round it. This space is to be filled with sand, so that the matrafs shall not touch the earthen vessel. The apparatus is then to be put into a furnace, and the whole to be made red hot. The fire must be applied gradually, that any oily or fuliginous matter may be expelled; after which, when the matrafs is made red hot, sulphureous vapours exhale: this degree of heat is to be continued till a truly sulphureous flame, which appears at the end of the operation, has been seen nearly a quarter of an hour: the fire is then to be extinguished, and the matrafs left to cool, without taking it out of the crucible; when it ceases to be red hot, it must be stopped with a cork. Before the matrafs is perfectly cold, it must be taken out of the crucible, and the powder it contains poured as quickly as possible into a very dry glass phial, with a glass stopper. If we would preserve this phosphorus a long time, the bottle containing it must be opened as seldom as possible. Sometimes it kindles while it is pouring into the glass phial; but it may be then extinguished by closing the phial expeditiously. A small quantity of this pyrophorus laid on paper, and exposed to the air, immediately takes fire, becomes red like burning coals, and emits a strong sulphureous vapour greatly resembling that which arises on decomposing liver of sulphur.

¹⁴¹⁷ Is not injured by mere exposure to light.

It has been generally alleged, that the common black phosphorus is impaired by being exposed to the light; but Mr Cavallo has discovered the fallacy of this supposition by the following experiment. Some portions of the same pyrophorus were inclosed in three glass tubes, and immediately sealed up hermetically. On the 20th of May 1779, two of them were suspended from a nail out of a window, and the third was wrapped up in paper and inclosed in a box, where not the least glimmering of light could enter. In this situation they were left for more than a year; after which one of those that had been kept out of the window was broke, along with that which had been kept in the dark, in the presence of Mr Kirwan; when the pyrophorus seemed to be equally good in each tube, taking fire in about half a minute after it was taken out of the tubes, and exposed to the air on a piece of paper.

¹⁴¹⁸ Cause of the accension.

There are many different kinds of pyrophori; some of the most remarkable of which are described under the article PYROPHORUS. Many theories have been invented to solve the phenomenon of their accension on the contact of air. This has been thought owing to the conversion of the earth of alum into lime, or to a remainder of the vitriolic acid attracting moisture from the atmosphere; but the formation of pyrophorus without either alum or vitriolic acid, shows that neither of these opinions can be just. It is most probable, therefore, that the heat is occasioned by the total dissipation of that aqueous part which is essential to the constitution of terrestrial substances. In consequence of this, the water contained in the atmosphere is not only attracted with avidity, but decomposed by the

matter reduced to such a state of extreme dryness. By these operations it gives out the latent heat contained in it, and this produces the accension in question.

Oils.

§ 2. ARDENT SPIRITS.

See FERMENTATION and DISTILLATION.

§ 3. OILS.

1. *Essential Oils.* Those oils are called *essential* which ¹⁴¹⁹Essential have evidently the smell of the vegetable from which oils. they are drawn. For the method of procuring them, see DISTILLATION. They are distinguished from all others by their superior volatility, which is so great as to cause them rise with the heat of boiling water. All these have a strong aromatic smell, and an acrid, caustic taste; in which respect also they differ from other oils. This taste is thought to proceed from a copious ¹⁴²⁰Supposed and disengaged acid, with which they are all penetrated. The presence of this disengaged acid in essential oils, appears from the impression they make upon the corks of bottles in which they are kept. These corks are always stained of a yellow colour, and a little corroded, nearly as they are by nitrous acid. The vapour of these oils also reddens blue paper, and converts alkalies into neutral salts.

This acid is likewise supposed to be the cause of their ¹⁴²¹Of their solubility in spirit of wine. They are not all equally solubility in soluble in this menstruum, because they do not all contain an equal quantity of acid. As this acid is much spirit of wine. disengaged, they lose a great deal of it by repeated distillations, and therefore they become less and less soluble on being frequently distilled. By evaporation they lose their most volatile and thin part, in which the specific smell of the vegetable from which they are extracted resides; by which loss they become thick, and acquire the smell and consistence of turpentine, and even of resins. In this state they are no longer volatile with the heat of boiling water; and, if distilled with a stronger fire, they give over an oil which has neither smell nor taste of the vegetable whence they were extracted, but is entirely empyreumatic, and similar to those oils procured by distilling vegetable or animal substances with a strong fire. See DISTILLATION.

To the class of essential oils, the volatile concrete ¹⁴²²Camphor. called *camphor* seems most properly to belong. With them it agrees in its properties of inflammability, solubility in spirit of wine, and a strong aromatic flavour. The only differences between them are, that camphor is always in a solid state, and is incapable of decomposition by any number of sublimations.

It has, however, been found possible to decompose ¹⁴²³Decomposed by distillation with certain additions. By distilling it several times along with bole, we obtain a fluid having the properties of an essential oil, soluble in water, and separating again on the addition of spirit of wine.

On distilling it eight times with dephlogisticated ¹⁴²⁴With dephlogisticated nitrous acid. nitrous acid, we obtain a salt having the form of a parallelepiped, of an acid and bitter taste, and changing the juice of violets and turnsole red. This has the properties of a true acid; combines with fixed and volatile alkalies into neutral salts capable of being crystallized; dissolves copper, iron, bismuth, arsenic, and cobalt.

Oils.

cobalt. With manganese it forms regular crystals, in some measure resembling basalt. It is distinguished from the acid of sugar by not precipitating lime from its solution in marine acid, and by forming with magnesia a white powder soluble in water.

According to Neumann, all the camphor made use of is the produce of two species of trees; the one growing in Sumatra and Borneo, the other in Japan. Of these, the Japan kind is the only one brought into Europe. The tree is about the size of a large lime, the flowers white, and the fruit a small red berry. All parts of the tree are impregnated with camphor; but the roots contain most, and therefore are chiefly made use of for the preparation of this commodity; though, in want of them, the wood and leaves are sometimes mixed.

The camphor is extracted by distillation with water in large iron pots filled with earthen heads stuffed with straw; greatest part of the camphor concretes among the straw, but part passes down into the receiver among the water. In this state it is found in small bits like gray salt-petre, or common bay-salt; and requires to be purified either by a second sublimation, or by dissolution in spirit of wine, filtration, and exsiccation. If the first method is followed, there will be some difficulty in giving it the form of a perfect transparent cake. A difficulty of this kind indeed always occurs in sublimations; and the only way is to keep the upper part of the glass of such a degree of heat as may keep the sublimate in a half-melted state. Dr Lewis recommends the depuration of camphor by spirit of wine, and then melting it into a cake in the bottom of a glass.

Camphor possesses considerable antiseptic virtues; and is a good diaphoretic, without heating the constitution; with which intention it is often used in medicine. It is likewise employed in fire-works and several other arts, particularly in making varnishes. See VARNISH.

1425
Soluble in
ardent spi-
rits and oil.

This substance dissolves easily and plentifully in vinous spirits and in oils; four ounces of spirit of wine will dissolve three of camphor. On distilling the mixture, the spirit rises first, very little camphor coming over with it. This shows that camphor, however volatile it may seem by its smell, is very far from having the volatility of ether, and consequently is improperly classed with substances of that kind.

1426
Empyreu-
matic oils.

2. *Empyreumatic Oils.* Under this name are comprehended all those oils, from whatever substance obtained, which require a greater heat for their distillation than that of boiling water. These are partially soluble in spirit of wine, and become more and more so by repeated distillations. The empyreumatic oils obtained from animal substances are at first more fetid than those procured from vegetables; but by repeated distillations, they become exceedingly attenuated and volatile, becoming almost as white, thin, and volatile, as ether. They then acquire a property of acting upon the brain and nervous system, and of allaying its irregular movements, which is common to them with all other inflammable matters when highly attenuated and very volatile; but this kind of oil is particularly recommended in epileptic and convulsive affections. It is given from 4 to 10 or 12 drops: but, though prepared with the utmost care, it is very susceptible of

losing its whiteness, and even its thinness, by a short exposure to air; which proceeds from the almost instantaneous evaporation of its more thin and volatile parts, and from the property which the less volatile remainder has of acquiring colour. To avoid this inconvenience, it must be put, as soon as it is made, into very clean glass bottles with glass stoppers, and exposed to the air as little as possible.

The most important observations concerning the method of making the pure animal oil are, first to change the vessels at each distillation, or at least to make them perfectly clean; for a very small quantity of the thicker and less volatile part is sufficient to spoil a large quantity of that which is more rectified. In the second place, Mr Beaumé has observed, that this operation may be greatly abridged, by taking care to receive none but the most volatile part in each distillation, and to leave a large residuum, which is to be neglected, and only the more volatile part to be further rectified. By this method a considerable quantity of fine oil may be obtained at three or four distillations, which could not otherwise be obtained at fifty or sixty.

3. *Animal Fats.* Though these differ considerably from one another in their external appearance, and probably in their medicinal qualities, they afford, on a chemical analysis, products similar in quality, and differing but inconsiderably in quantity. They all yield a large proportion of oil, and no volatile salt; in which respect they differ from all other animal substances. Two ounces of hog's lard yielded, according to Neumann, two drachms of an empyreumatic liquor, and one ounce five drachms and 50 grains of a clear brown-coloured oil of a volatile smell, somewhat like horse-radish. The *caput mortuum* was of a shining black colour, and weighed 10 grains.

Tallow being distilled in the same manner, two drachms of empyreumatic liquor were obtained from two ounces of it; of a clear brown oil, smelling like horse-radish, one ounce six drachms and 12 grains. The remaining coal was of a shining black colour, and weighed 18 grains. A particular kind of acid is now found to be contained in it.

The marrow of bones differs a little from fats, when chemically examined. Four ounces of fresh marrow, distilled in the usual manner, gave over three drachms and a scruple of a liquor which smelled like tallow; two scruples and an half of a liquor which had more of an empyreumatic and a sourish smell; two ounces and an half of a yellowish-brown, butyraceous oil, which smelled like horse-radish; and six drachms and an half of a blackish-brown oil of the same smell. The *caput mortuum* weighed four scruples.

All animal fats, when perfectly pure, burn totally away without leaving any feces, and have no particular smell. In the state in which we commonly find them, however, they are exceedingly apt to turn rancid, and emit a most disagreeable and noxious smell; and to this they are peculiarly liable, when long kept in a gentle degree of heat. In this state, too, an inflammable vapour arises from them, which when on fire is capable of producing explosions. Hence, in those works where large bellows are used, they have been often suddenly burst by the inflammable vapours arising from the rancid oil employed for softening the leather.

leather. The expressed unctuous oils of vegetables are subject to the same changes: but from this rancidity they may all be freed most effectually, by the simple process of agitating them well with water; which is to be drawn off, and fresh quantities added, till it comes off at last clear and insipid, without any ill smell. The proper instrument for performing this operation in large is a barrel-churn, having in it four rows of narrow split deals, from the centre to the circumference, each piece set at obtuse angles to the other, in order to give different directions to the oil and water as the churn turns round, thereby to mix them more intimately. The churn is to be swiftly turned round for a few minutes; and must then be left at rest, till the oil and water have fully separated; which will be in 15 or 20 minutes, more or less, according to the size of the churn. When this water is drawn off, fresh water is to be put in, and the churn again turned round, and this continued till the oil is perfectly sweet. If the oil and water are allowed to stand together for some days, a gelatinous substance is found between them, which is not very easily miscible either with oil or water. Chalk, quicklime, and alkaline salts, are found also capable of taking off the rancidity from oils and fats; but have the inconvenience of destroying a part of their substance.

§ 4. RESINS and BALSAMS.

THESE are commonly reckoned to be composed of an essential oil thickened by an acid; as the essential oils themselves are found to be convertible into a similar substance, by the exhalation of their more volatile parts. True resins are generally transparent in a considerable degree, soluble in spirit of wine, and possessed of a considerable degree of flavour.

Refins are originally produced by inspissating the natural juices which flow from incisions made in the stems of growing vegetables, and are in that state called *balsams*. The balsams may be considered as essential oils thickened by losing some of their odoriferous principle, and of their finest and most volatile part. There are several kinds of balsams, which, however, differ from each other only in the smell and degree of consistence; and therefore all yield similar products on distillation. An analysis of turpentine therefore will be sufficient as an example of the analysis and natural properties of all the rest.

The true turpentine-tree is found in Spain and the southern parts of France, as well as in the island of Chio and in the Indies. It is a middling-sized evergreen tree, with leaves like those of the bay, bearing purplish, imperfect flowers; and on separate pedicles hard unctuous berries like those of juniper. It is extremely resinous; and unless the resin is discharged, decays, produces fungous excrescences, swells, bursts, and dies; the prevention of which consists wholly in plentiful bleeding, both in the trunk and branches. The juice is the *Chio* or *Cyprus turpentine* of the shops. This sort is quite of a thick consistence, of a greenish white colour, clear and transparent, and of scarcely any taste or smell.

The kind now called *Venice turpentine*, is no other than a mixture of eight parts of common yellow or black rosin with five parts of oil of turpentine. What

was originally Venice turpentine is now unknown. Neumann relates, that the Venice turpentine sold in his country was no other than that prepared from the larix tree, which grows plentifully in some parts of France, as also in Austria, Tyrol, Italy, Spain, &c. Of this there are two kinds; the young trees yielding a thin limpid juice, resembling balsam of copaiba; the older, a yellower and thicker one.

The *Straßburg turpentine* is extracted from the silver-fir. Dr Lewis takes notice that some of the exotic firs afford balsams, or resins, superior to those obtained from the native European ones; as particularly that called *balm of Gilead fir*, which is now naturalized to our own climate. A large quantity of an elegant resinous juice may be collected from the cones of this tree: the leaves also, when rubbed, emit a fragrant smell; and yield, with rectified spirit, an agreeable resinous extract.

The common turpentine is prepared from different sorts of the pine; and is quite thick, white, and opaque. Even this is often counterfeited by mixtures of rosin and common expressed oils.

All the turpentines yield a considerable proportion of essential oil. From sixteen ounces of Venice turpentine, Neumann obtained, by distillation with water, four ounces and three drachms of oil. The same quantity distilled, without addition, in the heat of a water-bath, gave but two ounces and an half; and from the residuum treated with water, only an ounce could be obtained. The water remaining in the still is found to have imbibed nothing from the turpentine; on the contrary, the turpentine is found to imbibe part of the water; the residuum and the oil amounting to a full ounce on the pound more than the turpentine employed. When turpentine is distilled or boiled with water till it becomes solid, it appears yellowish; when the process is further continued, of a reddish brown colour: in the first state, it is called *boiled turpentine*; and in the latter, *colophony*, or *rosin*.

On distilling sixteen ounces of turpentine in a retort with an open fire, increased by degrees, we obtain first four ounces of a limpid colourless oil; then two ounces and two drachms of a yellowish one; four ounces and three drachms of a thicker yellow oil; and two ounces and one drachm of a dark brownish red empyreumatic oil, of the consistence of balsam, and commonly called *balsam of turpentine*.

The limpid essential oil called *spirit of turpentine*, is exceedingly difficult of solution in spirit of wine; tho' turpentine itself dissolves with great ease. One part of the oil may indeed be dissolved in seven parts of rectified spirit; but on standing for some time, the greatest part of the oil subsides to the bottom, a much greater proportion of spirit being requisite to keep it dissolved.

2. *Benzoin*. This is a very brittle brownish resin, of an exceedingly fragrant smell. The tree which produces benzoin is a native of the East Indies; particularly of Siam and the island of Sumatra. It is never permitted to exceed the sixth year; being, after this time, unfit for producing the benzoin. It is then cut down, and its place supplied by a young tree raised commonly from the fruit. One tree does not yield above three pounds of benzoin.

A tree supposed to be the same with that which affords

Bitumens.

fords benzoin in the East Indies, is plentiful also in Virginia and Carolina; from whence it has been brought into England; where it grows with vigour in the open ground. The bark and the leaves have the smell of benzoin; and yield with rectified spirit a resin of the same smell; but no resin has been observed to issue from it naturally in this climate; nor has any benzoin been collected from it in America.

1440
Soluble in
spirit of
wine.

Benzoin dissolves totally in spirit of wine into a blood-red liquor, leaving only the impurities, which commonly amount to no more than a scruple on an ounce. To water, it gives out a portion of saline matter of a peculiar kind, volatile and sublimable in the fire. See 984 *et seq.*

The principal use of resins is in the making of lacquers, varnishes, &c. See VARNISH.

§ 5. BITUMENS.

THESE are inflammable mineral bodies, not sulphureous, or only casually impregnated with sulphur. They are of various degrees of consistency; and seem, in the mineral kingdom, to correspond with the oils and resins in the vegetable.

1441
Origin of
bitumens.

Concerning the origin of bitumens, chemists are not at all agreed. Some chemical writers, particularly Mr Macquer, imagine bitumens to be no other than vegetable resins altered in a particular manner by the admixture of some of the mineral acids in the earth; but Dr Lewis is of a contrary opinion, for the following reasons.

"Mineral bitumens are very different in their qualities from vegetable resins: and, in the mineral kingdom, we find a fluid oil very different from vegetable oils. The mineral oil is changed by mineral acids into a substance greatly resembling bitumens; and the vegetable oils are changed by the same acids into substances greatly resembling the natural resins.

"From bitumens we obtain, by distillation, the mineral oil, and from resins the vegetable oil, distinct in their qualities as at first. Vegetable oils and resins have been treated with all the known mineral acids; but have never yielded any thing similar to the mineral bitumens. It seems, therefore, as if the oily products of the two kingdoms were essentially and specifically different. The laws of chemical inquiries at least demand, that we do not look upon them any otherwise, till we are able to produce from one a substance similar to the other. When this shall be done, and not before, the presumption that nature effects the same change in the bowels of the earth, will be of some weight."

1442
Naphtha.

There is a perfectly fluid, thin bitumen, or mineral oil, called *naphtha*, clear and colourless as crystal; of a strong smell; extremely subtle; so light as to swim on all known liquors, ether perhaps excepted; spreading to a vast surface on water, and exhibiting rainbow colours; highly inflammable: formerly made use of in the composition of the supposed inextinguishable greek fire.

1443
Petroleum.

Next to this in consistence is the *oleum petra*, or *petroleum*; which is grosser and thicker than naphtha, of a yellowish, reddish, or brownish colour; but very light, so as to swim even on spirit of wine. By distillation, the petroleum becomes thinner and more

subtile, a gross matter being left behind; it does not, however, easily arise, nor does it totally lose its colour by this process, without particular managements or additions.

Bitumens.

Both naphtha and petroleum are found plentifully in some parts of Persia, trickling through rocks or swimming on the surface of waters. Kempfer gives an account of two springs near Baku; one affording naphtha, which it receives in drops from subterraneous veins; the other, a blackish and more fetid petroleum, which comes from Mount Caucasus. The naphtha is collected for making varnishes; the petroleum is collected in pits, and sent to different places for lamps and torches.

Native petrolea are likewise found in many different places, but are not to be had in the shops; what is sold there for petroleum, being generally oil of turpentine coloured with alkanet root. The true naphtha is recommended against disorders of the nerves, pains, cramps, and contractions of the limbs, &c. but genuine naphtha is rarely or never brought to this country.

There are some bitumens, such as amber, ambergrease, pit-coal, and jet, perfectly solid; others, such as Barbadoes tar, of a middle consistence between fluid and solid. Turf and peat are likewise thought to belong to this class.

1. *Amber*. This substance melts, and burns in the fire, emitting a strong peculiar smell. Distilled in a strong heat, it yields a phlegm, an oil, and a particular species of acid salt. The distillation is performed in earthen or glass retorts, frequently with the addition of sand, sea-salt, coals, &c. which may break the tenacity of the melted mass, so as to keep it from swelling up, which it is apt to do by itself. These additions, however, make a perceptible difference in the produce of the distillation: with some the salt proves yellowish and dry; with others, brownish or blackish, and unctuous or soft like an extract: with some, the oil is throughout of a dark brown colour; with others, it proves externally green or greenish; with elixated ashes, in particular, it is of a fine green. The quantity of oil and phlegm is greatest when coals are used, and that of salt when sea-salt is used.

1444
Amber.

The most advantageous method of distilling amber, however, is without any addition; and this is the method used in Prussia, where the greatest quantities of salt and oil of amber are made. At first a phlegmatic liquor distils; then a fluid oil; afterwards one that is thicker and more ponderous; and last of all, an oil still more ponderous along with the salt. In order to collect the salt more perfectly, the receiver is frequently changed; and the phlegm, and light oil, which arise at first, are kept by themselves. The salt is purified, by being kept some time on bibulous paper, which absorbs a part of the oil; and changing the paper as long as it receives any oily stain. For the further depuration as well as the nature of this salt, see SUCCINUM.

1445
Most ad-
vantage-
ously di-
stilled with-
out addi-
tion.

2. *Ambergrease*. This concrete, which is only used as a perfume, yields, on distillation, products of a similar nature to that of amber, excepting that the volatile salt is in much less quantity. See AMBERGREASE.

1446
Amber-
grease.

3. *Pit-coal*. See the articles COAL and LITHAN-Pit-coal.

1447
Pit-coal.

THRAU.

Bitumens.

THRAX. This substance yields by distillation, according to the translator of the Chemical Dictionary, 1. phlegm, or water; 2. a very acid liquor; 3. a thin oil, like naphtha; 4. a thicker oil, resembling petroleum, which falls to the bottom of the former, and which rises with a violent fire; 5. an acid, concrete salt; 6. *an uninflamable earth* (we suppose he means a piece of charred coal, or cinder) remains in the retort. The fluid oil obtained from coals is said to be exceedingly inflammable, so as to burn upon the surface of water like naphtha itself.

1448
Peat.

4. *Peat*. There are very considerable differences in this substance, proceeding probably from the admixture of different minerals: for the substance of peat is plainly of vegetable origin; whence it is found to answer for the smelting of ores, and the reduction of metallic calces, nearly in the same manner as coals of wood. Some sorts yield, in burning, a very disagreeable smell, which extends to a great distance; whilst others are inoffensive. Some burn into grey or white, and others into red, ferruginous ashes. The ashes yield, on elixation, a small quantity of alkaline, and some neutral salt.

1449
Phenomena on distillation.

The smoke of peat does not preserve or harden flesh like that of wood; and the foot into which it condenses is more apt to liquefy in moist weather. On distilling peat in close vessels, there arises a clear insipid phlegm; an acid liquor, which is succeeded by an alkaline one; and a dark-coloured oil. The oil has a very pungent taste, and an empyreumatic smell; less fetid than that of animal substances, but more so than that of mineral bitumens. It congeals, in the cold, into a pitchy mass, which liquefies in a small heat: it readily catches fire from a candle; but burns less vehemently than other oils, and immediately goes out upon removing the external flame. It dissolves almost totally in rectified spirit of wine, into a dark, brownish-red, liquor.

§ 6. CHARCOAL.

1450
Differences between the coals of different substances.

THIS is the form to which all inflammable matters are reducible, by being subjected to the most vehement action of fire in close vessels; but though all the coals are nearly similar to one another in appearance, there is nevertheless a very considerable difference among them as to their qualities. Thus the charcoal of vegetables parts with its phlogiston very readily, and is easily reducible to white ashes; charred pit-coal, or, as it is commonly called, *coak*, much more difficultly; and the coals of burnt animal substances, far more difficultly than either of the two. Mr Macquer acquaints us, that the coal of bullock's blood parts with its phlogiston with the utmost difficulty. He kept it very red, in a shallow crucible, surrounded with charcoal, for six hours and more, stirring it constantly that it might be all exposed to the air, without being able to reduce it to white, or even grey ashes. It still remained very black, and full of phlogiston. The coals of pure oils, or concrete oily substances, and foot, which is a kind of coal raised during the inflammation of oils, are as difficultly burnt as animal coals. These coals contain very little saline matter, and their ashes furnish no alkali. These coals, which are so difficultly burnt, are also less capable of inflaming with nitre than others more combustible; and some of

them, in a great measure, resist even the action of nitre itself.

Vegetable and Animal Substances.

Charcoal is the most refractory substance in nature; no instance having been known of its ever being melted, or showing the least disposition to fusion, either by itself, or with additions: hence, charcoal is found to be the most proper support for such bodies as are to be exposed to the focus of a large burning glass. The only true solvent of charcoal is *hepar sulphuris*. By the violent heat of a burning-glass, however, it is found to be entirely dissolvable into inflammable air, without having any residuum. See AEROLOGY, n° 129. and CHARCOAL.

1451
Charcoal perfectly refractory.

The different substances mixed with different coals, render some kinds of charcoal much less fit to be used in reviving metals from their calces, or in smelting them originally from their ores. The coals of vegetable substances are found to answer best for this purpose. See METALLURGY.

SECT. V. Vegetable and Animal Substances.

THE only substances afforded by vegetables or animals, which we have not yet examined, are the mucilaginous, or gummy; and the colouring parts obtained by infusion, or boiling in water; and the calculous concretions found in the bodies of animals, chiefly in the human bladder. The colouring matter is treated of under the article *COLOUR-Making*, to which we refer; and in this section shall only consider the nature of the others.

§ 1. MUCILAGE or GUM.

THE mucilage of vegetables is a clear transparent substance, which has little or no taste or smell, the consistence of which is thick, ropy, and tenacious, when united with a certain quantity of superabundant water. It is entirely and intimately soluble in water, and contains no disengaged acid or alkali.

1452
Mucilages.

When mucilage is dissolved in a large quantity of water, it does not sensibly alter the consistence of the liquor: but, by evaporation, the water grows more and more thick; and, at last, the matter acquires the consistence of gum-arabic, or glue; and this without losing its transparency, provided a heat not exceeding that of boiling water has been used.

Gums, and solid mucilages, when well dried and very hard, are not liquefied in the fire like resins, but swell, and emit many fumes; which are, at first, watery; then oily, fuliginous, and acrid. Distilled in close vessels, an aqueous acid liquor comes over, along with an empyreumatic oil, as from other vegetable substances; a considerable quantity of coal remains, which burns to ashes with difficulty.

1453
Phenomena on distillation.

Mucilages and gums are not soluble either by oils, spirit of wine, alkalies, or acids, except in so far as they dissolve in these liquors by means of the water in which the alkali or acid are dissolved. They are, however, the most effectual means of uniting oil with water. Three parts of mucilage, poured upon one part of oil, will incorporate with it by trituration or agitation; and the compound will be soluble in water. Vegetable gums are used in medicine, as well as the mechanic arts: but the particular uses to which each of them is applicable, will be mentioned under the name of each particular gum.

Calculus.

1454
Jelly and
glue.

The mucilage obtained from animal substances, when not too thick, is called *jelly*, or *gelatinous matter*; when further inspissated, the matter becomes quite solid in the cold, and is called *glue*. If the evaporation is still further continued, the matter acquires the consistence of horn.

This gelatinous substance seems to be the only true animal one; for all parts of the body, by long continued boiling, are reducible to a jelly, the hardest bones not excepted. Animal jelly, as well as vegetable mucilage, is almost insipid and inodorous; but, though it is difficult to describe the difference betwixt them when apart, it is very easily perceived when they are both together. Acids and alkalies, particularly the latter, dissolve animal jellies with great ease; but the nature of these combinations is not yet understood. The other properties of this substance are common to it with the vegetable gums, except only that the animal mucilage forms a much stronger cement than any vegetable gum; and is therefore much employed for mechanical purposes, under the name of *glue*. See *GLUE*, and *ISINGLASS*.

§ 2. Of the HUMAN CALCULUS.

1455
Scheele's
experiments on
the human calculus.

THIS substance has been repeatedly examined by the most eminent chemists. Mr Scheele, as has been related n° 982, *et seq.* has been able to extract an acid from it. His account of it in other respects is to the following purpose.

1. All the calculi examined, whether flat and polished, or rough and angular, were of the same nature, and consisted of the same constituent parts.

2. The diluted vitriolic acid has no effect upon the calculus, but the concentrated acid dissolves it, and by abstraction from it is converted into the sulphureous kind, leaving a black coal behind.

3. Neither diluted nor concentrated spirit of salt had any effect upon it.

4. By means of nitrous acid, a new one was produced, and which is possessed of singular qualities, as already mentioned.

5. The solution of calculus in nitrous acid is not precipitated by ponderous earth, nor are metallic solutions sensibly altered by it.

6. It is not precipitated by alkalies, but grows somewhat yellower by a superabundance of the latter. In a strong digesting heat the liquor becomes red, and tinges the skin of the same colour. It precipitates green vitriol of a black colour; vitriol of copper, green; silver, grey; corrosive sublimate, zinc, and lead, white.

7. The solution is decomposed by lime-water, and lets fall a white precipitate, soluble in the muriatic acid without any effervescence: but though there be an excess of precipitate, the liquor still remains acid; which happens also with animal earth, and that of fluor dissolved in the same acids. On evaporation to dryness, the matter will at last take fire; but when heated only to a dull red heat in a close crucible, it grows black, smells like burnt alum, and effervesces with acids; being convertible before the blow-pipe into quicklime.

8. Neither this solution, nor the alkaline mixture, is changed by the acid of sugar.

9. The calculus is not changed by acid of tartar, though it is dissolved even in the cold by alkali, when reduced to such a state of causticity as not to discover the least mark of aerial acid. The solution is yellow,

and tastes sweetish; and is precipitated by all the acids, even by the aerial. It decomposes metallic solutions, but does not precipitate lime-water; and a smell of volatile alkali is produced by a little superabundance of alkali in the solution. Dry volatile alkali has no effect upon the calculus; but caustic volatile alkali dissolves it, though a pretty large quantity is required for this purpose.

10. Calculus is likewise dissolved by digesting in lime-water; and for this purpose four ounces of lime-water are required to twelve grains of the calculus; but the latter is partly precipitated by adding acids to the solution. By this union the lime-water loses its caustic taste.

11. Calculus is also dissolved entirely by pure water; but for this purpose a large quantity of fluid is required. Eight grains of calculus in fine powder will dissolve by boiling for a short time in five ounces of water. The solution reddens tincture of lacmus, but does not precipitate lime-water; and when it grows cold, the greatest part of the calculus separates in fine crystals.

12. On distilling a drachm of calculus in a glass retort, a volatile liquor was obtained resembling hartshorn, but without any oil; and in the neck of the vessel was a brown sublimate. On heating the retort thoroughly red hot, and then leaving it to cool, a black coal was left, weighing 12 grains, which retained its black colour on a red hot iron in the open air. The sublimate, which had some marks of fusion, weighed 28 grains, and became white by a new sublimation. Its taste was somewhat sourish, but it had no smell; it was soluble both in water and in spirit of wine; but a larger quantity of spirit than of water was requisite for this purpose. It did not precipitate lime-water, and seemed in some respects to agree with the sal succini.

From these experiments our author concludes, that the human calculus is neither calcareous nor gypseous; but consists of an oily, dry, volatile acid, united with some gelatinous matter. The calculus is an oily salt, in which the acid prevails a little, since it is soluble in pure water; and this solution reddens the tincture of lacmus. That it contains phlogiston, appears from its solution in caustic alkalies and lime-water, but especially from the effects of the nitrous acid, by which it acquires quite different properties than from solution in alkalies; nor can it be precipitated from this solution. The animal gelatinous substance appears on distillation, by which a liquor is obtained resembling spirit of hartshorn, and a fine coal is left behind.

13. Calculus is found dissolved in all urine, even in that of children. On evaporating four kannes of fresh urine to two ounces, a fine powder is deposited as it cools, and a part firmly adheres to the glass. The precipitated powder readily dissolves in a few drops of caustic fixed alkali; and has in other respects all the properties of calculus. Of the same nature is the lateritious sediment deposited by the urine of those who labour under an ague. Mr Scheele suspected at first, that there was in this urine some unknown menstruum which kept such a quantity of powder dissolved, and which might afterwards evaporate by exposure to the air; but altered his opinion on perceiving that the sediment was equally deposited in close vessels.

14. All urine contains some animal earth combined with phosphoric acid; by the superabundance of which acid,

1456
His conclusions concerning its composition.1457
Is found universally in urine.

Calculus. acid, the earth is kept dissolved; and by reason of this superabundant acid fresh urine communicates a red colour to lacmus. By saturation with caustic volatile alkali a white powder is precipitated; of which three drachms and an half are obtained from four kannes of urine. It is soluble in nitrous acid; and on adding the vitriolic, some gypsum is precipitated. On evaporating the nitrous acid, another remained, which precipitated lime-water; and when mixed with lamp-black, afforded phosphorus by distillation; whence it is evident, that the white powder just mentioned contained lime and phosphoric acid.

1458

mus.

1459
Salts, &c.
contained
in urine.

15. From these experiments Mr Scheele concludes, that all urine contains, besides the substances already known (*viz.* sal ammoniac, common salt, digestive salt, Glauber's salt, microcosmic salt, sal perlatum, and an oily extractive matter), a concrete acid, or that of calculus, and animal earth. It is also remarkable, that the urine of the sick is more acid, and contains more animal earth than that of healthy persons. With regard to the sal perlatum, it was afterwards discovered by Mr Scheele not to be a peculiar acid, but only a phosphoric acid disguised by a small quantity of fossil alkali united with it. The analysis is confirmed by synthesis; for, by combining fossil alkali with phosphoric acid, our author obtained a true perlate acid.

1460
Bergman's
account of
the calcu-
lus.

In a supplement to Mr Scheele's dissertation on the calculus, Mr Bergman observes, that he could not succeed in dissolving it entirely either in pure water or in the nitrous acid, though the undissolved part was the less in proportion to the fineness of the powder to which the calculus was reduced. The undissolved part appears most conspicuous, when small pieces, or small calculi of a few grains weight only, are put into a superabundant quantity of menstruum, and kept in a degree of heat very near to that which makes water boil. Here it will be observed, that the greatest part of the piece is dissolved; but that at the same time some small white spongy particles remain, which are not affected either by water, spirit of wine, acids, or caustic volatile alkali. If the liquor be made fully to boil, these particles divide into white rare flocculi, and become almost imperceptible, but without any entire dissolution. Mr Bergman could not collect a sufficient quantity of them to determine their nature with accuracy; only he observed, that when exposed to a strong heat, they were reduced to a coal which burns slowly to ashes, and is not soluble in diluted nitrous acid.

“When calculus vesicæ (says he) is dissolved in nitrous acid, no precipitation ensues on adding the acid of sugar; whence one is readily induced to conclude, that there is no calcareous earth present, because this experiment is the surest way to discover it. But I have found, in a variety of experiments concerning elective attractions, that the addition of a third substance, instead of disuniting two already united, often unites both very closely. That the same thing happens here I had the more reason to believe, because the acid of sugar contains some phlogistic matter, though of such a subtle nature, that, on being burned, it does not produce any sensible coal; and the event of my experiment has shown, that I was not mistaken in my conjecture. In order to ascertain this point, I burned coals of the calculus to ashes, which were quite white, and showed in every respect the same phenomena as lime; caused some effervescence during their solution

in acids, united with vitriolic acid into gypsum, were precipitated by the acid of sugar, and were partly soluble in pure water, &c. Notwithstanding this, there remains about one-hundredth part of the ashes insoluble in aquafortis; being the remainder of the substance above mentioned, which, together with the concrete acid, constitutes the calculus. If the calculus be dissolved in nitrous acid, the solution filtered and evaporated to dryness, and the dry mass calcined to whiteness, a calcareous powder is thus likewise obtained.”

Calculus.

As pure vitriolic acid contains no phlogiston, our author supposed, that by dropping it, in its concentrated state, into a solution of calculus in nitrous acid, the calcareous earth, if any existed in it, would be discovered. In this he was not disappointed; for when the solution was saturated, some small crystals were thus immediately separated. These, on examination, were found to be gypsum; and, after being dissolved in distilled water, were precipitated by acid of sugar. When the solution of calculus was very much diluted, no change appeared at first on the addition of oil of vitriol; but after a little evaporation, the above mentioned crystals began to appear. Some calculi of the bladder or kidneys at least certainly contain lime, but seldom more than one half in an hundred parts, or one in 200 parts.

1461
Calcareous
earth separated from
it by vitriolic acid.

By the assistance of heat, concentrated vitriolic acid dissolves the calculus with effervescence, and the solution is of a dark brown colour. On adding a little water, a kind of coagulation takes place; but by adding more, the liquor again becomes clear, and assumes a yellowish colour. Mr Bergman agrees with Mr Scheele in supposing that the muriatic acid has no effect upon the calculus; but he is in doubt whether it may not extract some part of the calcareous earth.

The red colour assumed by the solution of calculus in aquafortis is remarkable. A saturated solution discovers no smell of nitrous acid, and if evaporated by itself in a large open vessel, the liquor assumes at last a deep red colour, and scarcely contains any nitrous acid; for, on the one hand, paper tinged with lacmus scarce shows any redness; and, on the other, the colour is destroyed irrecoverably by the addition of any acid. By quick evaporation the solution at last swells into innumerable bubbles; the foam grows redder and redder, and at last becomes dark red after it is quite dry. This dry mass communicates its colour to a much larger quantity of water than before, and dissolves very readily in all acids, even such as have no action on the calculus; but they entirely destroy the colour, and that the more quickly in proportion to their degree of strength; even alum has this effect on account of the small quantity of loose acid it contains. Caustic alkalies also dissolve the colouring matter, and destroy it, but more slowly.

1462
Red colour
of the ni-
trous solu-
tion ac-
counted
for.

Our author endeavours to account for this red colour produced by the nitrous acid, from the peculiar nature of that acid, and the effect it has upon phlogiston. In order to obtain it, a proportionable quantity of acid must be made use of, and it ought to be diluted, that there may be no danger of going beyond the necessary limit. If too much be used, it will not produce the proper effect; but, by reason of its superabundance, more or less, or even the whole, will be destroyed in proportion to the quantity. By pouring it in an undiluted state on powdered calculus, it is

Calculus.

converted in a few moments into mere foam. The acid of calculus is the more easily separated from the aquafortis by evaporation, as the latter is rendered more volatile by the inflammable particles of the former: alkali added to them both united does not produce any precipitation; a circumstance generally observed where two acids are united. In this case both the acids unite with the alkali, according to the different laws of their attraction. The red mass obtained after desiccation is, however, very different from the concentrated acid, such as is contained in the calculus; for it is of a darker colour, and very deliquescent: the least particle gives a rose colour to a very considerable quantity of water; but the muriatic and other strong acids always certainly destroy it; and, in a longer or shorter time, produce a colourless solution. This remarkable change depends, according to our author, more on the action of the nitrous acid upon the inflammable part, than upon any thing remaining behind.—Such red spots as are produced upon the skin by the solution, are likewise produced upon bones, glass, paper, and other substances; but more time is required for their becoming visible, though this too may be a little accelerated by means of heat.

1463
Experiments of
Mr Higgins on this
subject.

The following is an abstract of Mr Higgins's experiments upon this subject.

1. Eight hundred and forty grains of dry and well powdered calculus were introduced into a glass retort. It was taken from a laminated stone with a small nucleus, which was likewise laminated. The outward crust appeared very porous, but increased in density towards the centre. By the application of heat, an elastic fluid was first slowly extricated; and which, on examination, appeared to be composed of equal parts of fixed and phlogisticated air. The last portions came over very fast, and were attended with an urinous smell; and, by continuing the distillation, it became evident that fixed and alkaline air came over together without forming any union, as they ought, on the common principles of chemistry, to have done; though our author is at a loss to know why they did not unite, unless they were prevented by the small quantity of inflammable air which came over along with them.

From the beginning of the 10th measure, a black, charry, and greasy matter began to line the conical tube and air-vessel adapted to the retort; and as the process went on, the proportion of alkaline air decreased, while that of the inflammable air was augmented, until towards the end, when the last nine measures were all inflammable; after which no more would come over, though the retort was urged with a white heat. On breaking the distilling vessel, a black powder weighing 95 grains was found in it. On digesting this for an hour in ten ounces of distilled water, and then filtering and evaporating it to two ounces, a yellowish powder was precipitated, but no crystals were formed after standing a whole night. This powder was then separated by filtration, and the liquor evaporated to one ounce; during which time more powder was precipitated. It was then filtered a second time, and the liquor evaporated to half an ounce; when it began to deposit a white powder, and to emit a subacid astringent vapour, not unlike that of vitriolic acid. This white precipitate, when washed and

dried, amounted only to one grain, had a shining appearance, and felt very soft, not unlike mica in powder. It was not changed, but rather looked whiter by exposing it to a fierce heat for ten minutes. It dissolved in distilled water without being precipitated by caustic volatile alkali. Mineral alkali, acid of sugar, and nitrated terra ponderosa, rendered the solution turbid; whence our author inferred, that the powder in question was selenite.

After the separation of this powder, the remaining solution was evaporated to dryness with a gentle heat. During the evaporation it continued to emit subacid vapours, leaving eleven grains of a powder of a dirty yellow colour, having an aluminous taste. To this powder he added as much distilled water as was nearly sufficient to dissolve it; after which it was set by for three weeks. At the expiration of this term several small, transparent, and cubical crystals appeared on the side of the vessel above the surface of the solution; and these likewise had an aluminous taste. The whole was then dissolved in distilled water, and the solution filtered. Acid of sugar produced no change in the liquor for at least five minutes, but an immediate cloudiness took place on a mixture with volatile alkali; and on filtering the liquor it was again rendered turbid by mineral alkali, though the caustic alkali already predominated. Nitrated terra ponderosa threw down a copious precipitate, and Prussian alkali discovered a small quantity of iron. This aluminous solution left a yellow substance on the filter; which, when collected and dried, weighed only half a grain: it dissolved without effervescence in nitrous acid; acid of sugar caused no precipitation, but caustic volatile alkali threw down a precipitate which dissolved in distilled water. This solution was rendered turbid by the acid of sugar and muriated terra ponderosa, but no effect was produced by caustic volatile alkali or lime-water.

The yellow powder first deposited by the solution weighed two grains and a half, and by exposure to a strong heat acquired a deep orange colour. On digestion with distilled water, the insoluble part was reduced to three-fourths of a grain, and appeared to be iron; while the soluble part was found to be nothing else but gypsum. Our author, however, is of opinion, that this iron is impregnated with a small portion of vitriolic acid, though not in such quantity as to render it soluble.

The charred matter remaining in the retort was reduced by lixiviation with water to 80 grains. These were calcined with a red heat in an open fire, but could not be reduced to a grey powder in less than three quarters of an hour. When thoroughly calcined and cold, it weighed only 21 grains, which communicated to hot distilled water a limy taste, and gave it the property of turning syrup of violets green. Diluted vitriolic acid had no effect upon it, but it was rendered turbid by aerated volatile alkali and acid of sugar. The remainder when well dried weighed 16 grains, which dissolved in nitrous acid at first with a little effervescence; and when this ceased, the solution went on very slowly, until the whole was taken up. Acid of sugar made no change in the liquid, but the whole was precipitated by caustic volatile alkali. Prussian alkali threw down a grain, or perhaps more, of blue;

Calculus.

¹⁴⁶⁴ ^{His account of its component parts.} Calculus. blue; the precipitate digested with distilled vinegar lost a grain and an half, which was thrown down by caustic volatile alkali. The insoluble part being washed and digested in distilled water for half an hour, was partly dissolved; the solution was not affected by caustic volatile alkali, but acid of sugar and nitrated terra ponderosa caused an immediate cloudiness. Seven grains and an half of the powder, which was insoluble both in acetic acid and distilled water, were readily taken up by diluted vitriolic acid, and precipitated by caustic volatile alkali: the 16 grains last treated, therefore, appeared to contain, of clay $7\frac{1}{2}$ grains; of selenite, six grains; magnesia, one and a half; and of iron, one grain. The proportions of the different ingredients in the whole calculus, therefore, according to Mr Higgins, are as follow:

	Grains.
Iron	$2\frac{1}{2}$
Selenite	11
Clay	$7\frac{1}{2}$
Alum	8
Pure calcareous earth	5
Aerated magnesia	$1\frac{1}{2}$
Charry combustible substance	59

In all $94\frac{1}{2}$

¹⁴⁶⁵ ^{Experiments on the sublimate arising from it on distillation.} In this experiment, a darkish yellow sublimate adhered to the neck of the retort; the inner part next the retort more compact, but the rest of a lamellar spongy texture. This sublimate, when carefully collected, was found to weigh 425 grains, and readily dissolved in eight ounces of hot distilled water. A coaly substance was separated from this solution by filtration, which, when washed and dried, weighed ten grains, and when exposed to a red heat burned with a greenish flame, emitting white fumes, which smelled like vitriolic sal ammoniac: the residuum after calcination weighed half a grain, and was of a whitish colour; appearing insoluble in distilled water, but dissolving with effervescence in nitrous acid. Acid of sugar caused a very small precipitation, which did not take place until the mixture had stood for some time; but caustic volatile alkali instantly threw down a precipitate, which was taken up, when washed, by the acetic acid. The quantity was too small to be examined with greater accuracy; but it seemed to possess the properties of magnesia. The saline solution had the colour of small beer; and, when evaporated to two ounces, did not deposit any sediment, or yield any crystals. The black matter with which the conical tube and air vessel were lined, weighed 28 grains, and adhered so fast to the glass, that it was impossible to collect the whole from the fragments of the glass. When dissolved in distilled water and filtered, four grains of coals, similar to that obtained from the former, were procured; but no signs of crystallization were observed after evaporation to one ounce, and suffering the liquor to stand all night.

By this treatment the solution acquired the consistence of treacle; so that it was plainly not crystallizable, and therefore its analysis was plainly to be attempted after a different method. It was now put into a tubulated glass retort, together with six ounces of distilled water to wash it down. By distillation in a sand-bath three ounces of water were procured, which dif-

fered in nothing from common distilled water, but in being coloured with a small quantity of the solution from the neck of the retort. On changing the receiver, about half an ounce of liquor of the same kind came over, after which the distillation began to be attended with an urinous smell. This continued barely perceptible for some time; but when about an ounce and an half had passed over, it became so very pungent, that our author could no longer doubt of its being in a caustic state. A small quantity of mild alkali, however, adhered to the lower part of the neck of the retort, some of which was washed down by the distillation; so that the proportions betwixt the two could not be ascertained. The volatile alkaline solution in the retort had the colour of spirit of hartshorn, and like it became darker coloured by the contact of air; on account of the evaporation of part of the alkali, and the rest becoming less capable of suspending the coaly matter mixed with it.

After all the liquor had passed over, and nothing remained in the retort but a small quantity of black matter, the fire was raised; and, as the heat increased, this black substance acquired a white colour, with a kind of arrangement on the surface, which was occasioned by the heat applied to the bottom of the retort being only sufficient to raise the salt to the top of the matter in the retort; but as the sand became nearly red-hot, white fumes began to appear, which condensed on the upper part of the retort, and a little way down the neck. The process lasted until the matter was nearly red-hot, when the fumes ceased, and nothing more passed over. The sublimate, when collected, was found to weigh 72 grains, a black porous brittle substance remaining on the bottom of the retort, which weighed 12 grains. This residuum, when exposed to a strong heat, emitted white fumes, with a slight alkaline smell; by which process it was reduced, with very little appearance of combustion, to a grey powder weighing three grains, which was accidentally lost.

Five grains of this purified sublimate, mixed with as much quicklime, emitted no smell of volatile alkali; and, when thrown upon a red-hot iron, emitted white fumes. The same effect was produced by a mixture of equal quantities of vegetable alkali and sublimate. The remainder, consisting of 62 grains, was divided into two equal parts; the one of which was mixed with two ounces of distilled water, and on the other was poured 60 grains of vitriolic acid diluted with half an ounce of water. These two mixtures being suffered to remain for six weeks, seemed to be but little acted upon. That with vitriolic acid was then put into a small matras, and boiled on sand for half an hour with two ounces of distilled water, when the whole was taken up. The solution looked clear, and deposited nothing on standing. Mild mineral alkali had no effect upon it; but mild vegetable alkali threw down a copious sediment in white flocculi, which was redissolved by caustic alkali, lime-water, and partly by mild mineral alkali. Phlogisticated alkali, acid of sugar, and acid of tartar, had no effect upon it. The other portion of sublimate, which had been mixed with distilled water, was very little dissolved; but in pouring it into a matras some small round lumps were observable on the bottom of the glass. These were

Calculus. six or seven in number, some weighing a whole grain, others not more than one-half. They were very hard and compact, with a smooth surface, and in figure resembling the nucleus of the original calculus. The whole was then put into a matrafs with about three ounces of water. On boiling it on sand for three quarters of an hour, about one-half of it was taken up: the solution passed the filter very clear whilst hot; but on cooling became turbid, and at last deposited white flocculi, which were redissolved on the addition of caustic volatile alkali and lime-water. It turned syrup of violets green; which, however, our author thinks might have been occasioned by its retaining volatile alkali, though it had not the smallest appearance of any such impregnation. He has nevertheless frequently observed, that sometimes the purest vegetable alkali contains volatile alkali, notwithstanding the various operations and degrees of heat it undergoes before it can be brought to the degree of purity at which it is called salt of tartar.

On filtering the solution to separate what had been deposited by cooling, no change was produced in the filtered liquor by mineral alkali; but mild vegetable alkali produced a cloudiness, which was instantly taken up on adding mineral alkali and lime-water. Neither Prussian alkali, nor the acids of arsenic, tartar, sugar, or borax, nor any of the three mineral acids, had any effect upon it.

1466
Experiments with
nitrous acid.

2. An hundred and twenty grains of the same calculus were put into a tubulated glass retort, and half an ounce of strong nitrous acid poured upon it. An effervescence immediately ensued; and some part of the extricated aerial fluid being preserved, appeared to be fixed air mixed with a small quantity of nitrous air. When the effervescence ceased, a quarter of an ounce more of nitrous acid was added. On digesting the mixture upon hot sand for an hour, it emitted nitrous vapour and nitrous air; but the latter in very small proportion. When the solution was completed, the whole was poured into a small matrafs, and gently boiled till the superabundant nitrous acid was nearly expelled. The solution was of a deep yellow colour and turbid; but on adding five ounces more of water, and digesting it for a quarter of an hour longer, it acquired the colour and consistency of dephlogisticated nitrous acid. On cooling it became somewhat turbid, and in a few days deposited a darkish yellow powder; which, when separated, washed, and dried, weighed little more than a quarter of a grain, and, on examination, was found to be a calx of iron.

1467
Crystallizes
on exposure
to the sun.

Our author being desirous to know what effect the sun would have upon it, placed it in a window where the sun shone full upon it for four hours every day. Here a little moisture seemed daily to exhale from it, the weather being hot, and the matrafs, which had a short wide neck, being only covered with bibulous paper to keep out the dust. In this situation, in the course of a week, a few very small crystals appeared to float upon the surface. These in time fell to the bottom, where they adhered together so as to form a hard concretion, still retaining a crystalline appearance, but so small and confused, that it was impossible to distinguish their figure; and this deposition of crystals continued for a month, after which it seemed to cease. The solution was then filtered to separate the salt; af-

ter which one-half of the liquor was evaporated away, and the rest set in the usual place for a fortnight longer, but no more crystals appeared. The salt, which weighed three grains, was then digested in four ounces of distilled water; but no part seemed to be dissolved. Three ounces of the water were then decanted off, and six drops of vitriolic acid added to the remainder, which by the help of digestion seemed to dissolve the salt slowly; but on adding half an ounce more distilled water, the whole was readily taken up. Acid of sugar had no effect on this solution; but lime-water rendered it turbid. The whole was then precipitated with caustic volatile alkali, and the solution filtered, which likewise threw down the lime from lime-water. The precipitate was then washed, and distilled vinegar poured upon it, which did not take it up; but it was dissolved by marine acid. Phlogisticated alkali had no effect upon it; and the acid of sugar occasioned very little cloudiness after standing three or four hours; from which our author supposed that the matter was phosphorated clay.

The solution, being now free from iron and phosphorated clay, had a subacid taste, and looked clearer, though still retaining a yellow cast. Acid of sugar had no effect upon it; but nitrated terra ponderosa threw down a precipitate, as did likewise the caustic volatile alkali. Mild vegetable alkali caused no precipitation; which our author attributed to the solution of the manganese and clay by the fixed air extricated from the alkali. Two-thirds of the solution were then put into a small glass retort, and two ounces distilled off, which had no taste, but smelled very agreeably, and not unlike rose-water. After all the liquor had passed over, white fumes appeared in the retort, and these were soon followed by an aerial fluid. On collecting some of this, a candle was found to burn in it with an enlarged flame. Nitrous air did not diminish it in the least; and it seemed to be that species of air into which nitrous ammoniac is convertible. No more than 13 or 14 inches of this kind of air could be obtained; and as soon as it ceased to come over, crystals were observed in the lower part of the neck of the retort. On augmenting the heat, a white salt began to sublime and adhere to the upper part of the retort; the operation was continued until the retort was red-hot; but, on breaking it, the quantity of sublimate was so small, that very little of it could be collected; though, from the small quantity obtained, our author was convinced of its being the same in quality with what was obtained in the former analysis. The salt which crystallized in the neck of the retort was nitrous ammoniac, as appeared from its detonation *per se*, &c. A grey powder was left in the bottom of the retort, which hot distilled water partly dissolved: muriated terra ponderosa, acid of sugar, and vegetable alkali, rendered this solution turbid; but caustic volatile alkali had no effect upon it. The remaining part of the powder which was left by the distilled water, readily dissolved with effervescence in the marine acid, and was precipitated by caustic volatile alkali; the part soluble in distilled water appearing to be gypsum, and that soluble in marine acid to be magnesia.

From all these experiments, Mr Higgins concludes the composition of the human calculus to be vastly different

Calculus. 1468 Higgins's account of the constituent parts of calculus. ferent from what either Mr Scheele or Mr Bergman have supposed it to be. "It appears (says he), that the calculus was composed of the following different compounds blended together; viz. selenite, alum, microcosmic salt, mild volatile alkali, lime, and caustic volatile alkali, combined with oil, so as to form a saponaceous mass; calx of iron, magnesia combined with aerial acid, clay enveloped by a saponaceous and oily matter, and the sublimate already described." Considering this to be the true state of the calculus in the bladder, the small proportions of clay, selenite, magnesia, and iron, which are the most insoluble of the ingredients; the great solubility of microcosmic salt and alum, and the miscibility of lime, volatile alkali, and oil, in water; tend to show, that the sublimate is the cementing ingredient. Indeed, its insolubility in water, and property of forming nuclei out of the body, as above observed, leave no room to doubt it. The proportion of the other ingredients, and very likely their presence, depend upon chance, volatile alkali and oil excepted; therefore this sublimate should be the object of our investigation.

1469 Remarks on the remedies proper for dissolving it.

Mr Higgins concludes his dissertation with some practical remarks concerning the remedies proper for dissolving the stone, for counteracting that disposition in the body which tends to produce it, and concerning the regimen proper for those who are to undergo the operation of cutting for it. "The effect of mild mineral alkali (says he) on the sublimate, is well worth the attention of those who may have an opportunity of trying its efficacy. Mild mineral alkali may be taken in large doses, and continued for a length of time with impunity to the most delicate constitutions, only observing a few circumstances; but this alkali, in a caustic state, must very often be attended with mischievous consequences. Besides, if we consider that it must enter the mass of blood before any part can reach the bladder, and the small portion of the dose taken secreted with the urine, and, lastly, the action of caustic alkali upon animal substances; we shall be at a loss to know on what principle caustic alkalies have been recommended in preference to mild. Soap itself might as well be recommended at once; for soon after caustic alkali is taken, it must be in a saponaceous state. Fixed vegetable alkali should be avoided, and the preference given to the other two alkalies. As it is evident that alkalies have no real action on the stone in the bladder, though their efficacy has been experienced in alleviating the disease when timely administered, their mode of action is only explicable in the following manner: They either prevent the generation of the sublimate in the system, or else keep it in solution in the mass of fluids; and being in the utmost degree of divisibility, its ultimate particles are capable of passing through the most minute excretories; by which means it is carried off by other secretions as well as the urinary. Thus the urine, not being saturated with this matter, acts as a solvent on the stone; and as the most soluble parts are first washed away, it falls through time into fragments of irregular surfaces, which by their friction irritate and inflame the bladder, as has been observed by several practitioners.

"Allowing that the sublimate is the cementing substance in the calculus, and judging, from the effects of

alkalies upon it, their *modus operandi* in the constitution, it remains now to inquire into the origin of the calculus. Mr Scheele has found this sublimate in the urine of different persons; and hence inferred, that it was a common secretion: but it still remains to be ascertained, whether there be a greater quantity of it procured from the urine of patients who labour under this disorder than in those who do not? If this should not be the case, may not a deficiency of volatile alkali in the constitution be the cause of concretions in the kidneys, bladder, &c.; or, which must have the same effect, too great a proportion of acid, which, uniting with the alkali, may take up that portion which would have kept the sublimate in solution until conveyed out of the system by the urinary and other secretions; and may not this be the phosphoric acid? If this latter should be the case, an increase of microcosmic salt must be found in the urine; but if the former, a decrease of the volatile alkali, and no increase of the neutral salt. The small quantity of phosphoric acid found in the calculus proceeds from the solubility of microcosmic salt. Do not volatile alkali and phosphoric acid constitute a great part of the human frame? and is there not a process continually carried on to generate these in the system? and is not this process liable to be retarded or checked by intemperance, &c. which may vary their quantities and proportions? and may not a due proportion of these be necessary to a vigorous and sound constitution? If so, no wonder that an increase or deficiency in either or both of these should be productive of several disorders."

On this subject, however, our author has not had sufficient leisure to make the experiments necessary for its elucidation. Indeed, it seems not easy to do so; as, in his opinion, at least 500 would be required for the purpose. "That the urinary sublimate is present in tubercles found in the lungs of persons who die of pulmonary consumptions, and likewise in what are vulgarly called *chalk stones*, is what I have experienced; but in what proportion, or whether in quantities sufficient to cause the concretion, is what I cannot say; for I have had but a few grains of each to examine. I have every reason to suspect, that consumptions and scorbutic complaints very frequently arise from a superabundance of this sublimate in the system; and that it is chiefly the cause of the gout and rheumatism, and solely the cause of the stone in the bladder. I make no doubt but these disorders generally proceed from obstructions; and it is probable, that either a precipitation of this sublimate in the system, or else a deficiency of some other secretion, which would hold it in solution until conveyed out of the body, may be the chief cause of those obstructions; and likewise, that different degrees of precipitation may produce different symptoms and disorders.

"That mineral or volatile alkali and bark have been useful in the above disorders, has been affirmed by experienced physicians; and I know an instance myself of mineral alkali and nitrous ammoniac being serviceable in a pulmonary complaint of some standing.

"With respect to the stone, when it acquires a certain magnitude, it is absurd to attempt to dissolve it in the bladder, it wastes so very slowly; and during this time the patient must suffer vast pain, particularly when

when the stone acquires a rugged surface: therefore cutting for it at once is much preferable.

"Mineral alkali taken in the beginning of the complaint, and before the stone accumulates, will no doubt check its progress, and may in time change that dis-

position in the habit. Patients who are cut for the stone should, I think, take mineral alkali for some time when the wound is healed; but not before, for fear of bringing on a mortification."

I. VITRIOLIC ETHER.

1471
Various
methods of
rectifying
vitriolic
ether.

M. PELLETIER formerly proposed a method of rectifying this fluid by putting manganese into the vessels; but as the vitriolated manganese might perhaps communicate some injurious quality, another method is proposed by M. Tingry. After first drawing off the ether, he adds a diluted solution of volatile alkali, and avoids as much as possible the dissipation of the vapours: the ether is then redistilled. It may afterwards in this way be washed more safely, and with less loss. The little proportion of the ether which is separated in the water, may be again recovered, or the water may be again employed for the same purpose. M. Lunel proposes calcined magnesia for this purpose, as its salt is not soluble; though perhaps pure terra ponderosa might be better.

II. NITROUS ACID.

1472
Mr Hig-
gins's ob-
servations.

ON this subject Mr Higgins has several curious and interesting observations. "It is not an easy matter (says he), to ascertain exactly the greatest quantity of dephlogisticated air, which a given quantity of nitrous acid may contain. I always found nitre to vary, not only in its product of phlogisticated and dephlogisticated air, but likewise in their proportion to one another. The purest nitre will yield, about the middle of the process, dephlogisticated air so pure as to contain only about $\frac{1}{3}$ of phlogisticated air. In the beginning, and nearly about the latter end of the process, air will be produced about twice better than common air. On mixing the different products of a quantity of pure nitre, it was found that, by exposure to liver of sulphur, $\frac{1}{8}$ part was left unabsorbed; and this was the utmost purity in which I obtained dephlogisticated air from nitre.

1473
Account of
its consti-
tuent parts
by M. La-
voisier.

"According to M. Lavoisier, 100 grains of nitrous acid contain $79\frac{1}{2}$ of dephlogisticated air, and $20\frac{1}{2}$ of phlogisticated air, which is not quite four to one. But his experiments contradict this; for whatever mode he adopted to decompose nitrous acid, it appeared that the proportion of dephlogisticated air was nearly as five to one of phlogisticated air.

1474
By Mr Ca-
vendish.

"Mr Cavendish has proved, that nitrous acid may be formed by taking the electric spark in a mixture of three parts of phlogisticated air, and seven of dephlogisticated air, which is but $\frac{1}{7}$ more of dephlogisticated air than nitrous air contains; which may apparently contradict M. Lavoisier's, as well as my own, estimation of the proportion of the constituent principles of ni-

N^o 75.

trous acid, when in its perfect state. The red nitrous vapour contains three parts of nitrous air and one of dephlogisticated air, or one of phlogisticated and three of dephlogisticated air; but nitrous vapour may be formed with a less proportion of dephlogisticated air; and which, though it may not be so condensable as a more perfect nitrous vapour, yet will, when in contact with pure alkali, unite with it, and form nitre, as was the case in the experiment of Mr Cavendish. The common straw-coloured nitrous acid contains more dephlogisticated air than the red nitrous acid or vapour; the proportion appears to be about four to one; but the colourless contains about five of dephlogisticated to one of phlogisticated air.

"Having once a charge of nitrous and vitriolic acid in a green glass retort, I put it in a sand pot to distil; but the pot being small, the edge came too near the retort, about a quarter of an inch or more above the charge; which, before the process commenced, and when it acquired more than the heat of boiling water, cracked it all round in that direction. Being thus situated, I was obliged to withdraw the fire, and, before the charge got cold, to ladle it into an earthen pan. On introducing it into a fresh retort, I obtained from it nitrous acid nearly as colourless as water. The vitriolic acid used in this process not being very perfect, the goodness of the nitrous acid was attributed to the purity of the nitre from whence it was distilled; but in another process, though the same nitre was used with much purer vitriolic acid, the produce was of an high straw colour. On recollecting the above-mentioned circumstance, the vitriolic acid and nitre were next mingled in due proportion, and exposed in an earthen pan set in sand, to nearly the heat of boiling water, for half an hour or more, continually exposing fresh surfaces to the air. When the charge was quite cold, I introduced it into a retort, and distilled as colourless nitrous acid as the former. As no nitrous air was emitted during digestion, it must have imbibed dephlogisticated air from the atmosphere."

Mr Proust found, that strong nitrous acid will set fire to charcoal if it be rendered very dry. He likewise remarked, that charcoal exposed to the air a few hours after calcination, was unfit for the experiment. Charcoal, he observes, attracts moisture very forcibly. The first effect of the charcoal on the nitrous acid, he observes, is to withdraw a portion of its water from it; by which it is rendered highly concentrated, at the same time that the condensation of the water heats the charcoal in a small degree, but sufficiently to volatilize a nitrous vapour; which, as soon as it reaches that portion of dry charcoal next the humid part, is condensed

Nitre. densed by it, and generates heat enough to promote the decomposition of the nitrous acid. Hence we see why the experiment will not succeed if the acid be poured on the surface of the charcoal.

¹⁴⁷⁷
Effect of
nitrous acid
on blood. The effect of nitrous acid on blood, according to Mr Higgins, is very singular. Two parts of blood procured fresh at the butchers, one of strong nitrous acid, and about one fifth of the whole of water, were digested in the heat nearly of boiling water (fresh portions of water being occasionally added until the whole of the acid was expelled), when it acquired almost the colour, and exactly the taste, of bile. When mixed with a large quantity of water, it acquired a fine yellow colour; and, on standing, deposited a substance of a brighter yellow, though the supernatant liquor still retained a yellow colour and bitter taste, but not so intensely as when the precipitate was suspended in it. The different stages of this process were well worthy of observation. No nitrous air was produced, and the acid was expelled in the state of a white vapour. The liquor was found to increase in bitterness as the acidity vanished. About the middle of the process, the solution first tasted acid, but was quickly succeeded by a bitter sensation. It appears that the nitrous acid took dephlogisticated air from the blood; for though red nitrous acid was used, it was expelled in a perfect state.

III. NITRE.

¹⁴⁷⁸
Nitre generated with-
out putre-
faction. THOUGH the artificial generation of the nitrous acid, from a mixture of dephlogisticated and phlogisticated air, is now sufficiently understood, yet we do not well know in what manner nature performs the operation. Some chemists, particularly M. Thouvenal, have found, that putrefaction favours the production of nitrous acid. All animal substances, during their decay, give out a vast quantity of phlogisticated air; therefore, if dephlogisticated air be present, it will unite to the phlogisticated air in its nascent state, and form nitrous acid: but Mr Higgins has observed, that nitrous acid may be generated in plenty where there is no putrid process going on. "The chemical laboratory at Oxford (says he) is near six feet lower than the surface of the earth. The walls are constructed with common limestone, and arched over with the same; the floor is also paved with stone. It is a large room, and very lofty. There are separate rooms for the chemical preparations, so that nothing is kept in the laboratory but the necessary implements for conducting experiments. There is an area adjoining it on a level with the floor, which, though not very large, is sufficient to admit a free circulation of air. The ashes and sweepings of the laboratory are deposited in it. There is a good sink in the centre of this area, so that no stagnated water can lodge there. Notwithstanding all this, the walls of the room afford fresh crops of nitre every three or four months. Dr Wall, who paid particular attention to this circumstance, and who told me it contained fixed vegetable alkali, requested I would analyse it, and let him know what it contained. I found that two ounces of it contained six drachms of nitrated fixed vegetable alkali, and three of calcareous nitre. The nitre first appears in small whitish filaments as fine as cob-web, which, when they

get a little larger, drop off; so that they never acquire sufficient growth to distinguish their figure to a naked eye. On finding that they contained fixed vegetable alkali, I concluded that it proceeded from minute vegetation; but in this I was mistaken; for I found that they were soluble in water, and that they detonated with charcoal at every stage of their growth. Having swept this saline efflorescence from the wall, I dug deep into it, but could not obtain nitre from it. When a part had been white-washed, it yielded nitre, but not so abundantly as a neighbouring spot which had not been treated in the same manner. Hence it is evident, that nitrous acid may be formed without the assistance of putrescent processes in a still damp air, where there is a substance to attract it when half formed, whereby it is in time brought to perfection. The above facts moreover prove, that fixed vegetable alkali is a compound."

IV. MARINE ACID.

¹⁴⁷⁹
Unsuccessful
attempts
to decom-
pose sea-
salt. Mr Higgins informs us, that he has, with a view to decompose sea-salt, mixed it with manganese in various proportions, and exposed them in a reverberating furnace in a well closed crucible for three hours, to a heat nearly sufficient to melt cast iron. In the same manner he treated manganese, salt, and charcoal, as well as clay, salt, and charcoal, and salt and clay alone, with very little success. He treated calcined bones, salt, and charcoal, and calcined bones and salt, as well as lime and salt, in the same manner, without effecting any apparent change in the salt. He was informed, however, by Mr Robertson, apothecary in Bishopsgate-street, that he had partially alkalized it, by exposing it with clay to a fierce heat; but that soon after it got into contact with air, it became neutral again. "If common salt and litharge be fused (says Mr Higgins), it is in part decomposed; the acid suffers no decomposition, but unites with the lead; whereby it acquires, when the saline matter is washed away, a yellow colour. It is evident (adds he) from these facts, that the basis of marine acid is a combustible body, and quite different from light inflammable air, charcoal, or any known inflammable substance; and that it attracts dephlogisticated air with greater force than any substance hitherto discovered. Though charcoal will decompose all other acids, except a few, when united to bodies which will fix them until they acquire a sufficient degree of heat, yet it has no effect on marine acid."

According to Fourcroy, if alkaline air be confined by mercury, and dephlogisticated marine acid air be added to it (which must be done quickly, as the acid air would dissolve the mercury), each bubble produces a slight detonation, and furnishes a very amusing spectacle.

¹⁴⁸⁰
Method of
distilling
spirit of
salt with
clay. Though in this country the distillation of spirit of salt with clay has long been entirely laid aside for the process with oil of vitriol, yet it is still practised in other countries, and may be effected in the following manner: Having previously decrepitated the salt, and dried the clay, they are then to be ground, mixed, and sifted together. The mixture is next to be worked with a spatula, and then with the hands, until it is brought into a moderately stiff and uniform mass.

Marine
Acid.

This is to be divided into balls about the size of a pigeon's egg, so that they can pass through the neck of the retort; but before they are put into the distilling vessel, it is proper to dry them thoroughly. The retorts must be of stone ware, and carefully coated, in order to prevent them from breaking with the intense heat to which they are exposed. They are to be filled two-thirds full of materials, and the distillation must be performed in a reverberatory furnace. The receiver at first is not luted on, because that which rises in the beginning of the distillation, being very aqueous, is to be put by itself. When this has come over, another receiver is then to be applied, and cemented with fat lute, and covered with a cloth daubed with a mixture of lime and the whites of eggs. The heat is to be raised until the retort is red-hot, and continued in this degree until the distillation ceases.

Various proportions of clay and salt have been recommended for this process; but it seems probable that not less than ten parts of clay to one of salt, as Pott has directed, will be found necessary. Instead of the clay, some direct the use of bole; but this is inconvenient, on account of the iron it contains. Powdered talc has also been recommended, but this is not always free from iron; and where a very pure spirit is wanted, there is a necessity for having recourse to oil of vitriol, and glass or stone-ware vessels. As the marine acid cannot be separated from the earthy mixtures above mentioned, but by means of moisture, M. Beaumé advises to moisten the residuum, and repeat the distillation, by which more acid will be obtained.

1481
Effect of
marine acid
upon phlo-
gistic mat-
ters.

As marine acid has very little action upon phlogistic matters, it cannot therefore affect oils, either expressed or essential, in a manner similar to the vitriolic or nitrous. M. Marges, however, has observed yellow crystals resembling amber formed in bottles, containing a mixture of oils and marine acid of moderate strength, which had stood for several months. The little effect which the marine acid has upon these substances was first supposed to be owing to its want of phlogiston in itself; but when it was afterwards found, that, by the application of certain substances which have a great attraction for phlogiston, the marine acid was rendered capable of uniting very readily with inflammable matters, the former theory was abandoned. It was now asserted, that the acid, instead of containing no phlogiston, was naturally endowed with a very considerable quantity; and that, in its new state, it was dephlogisticated by the substances applied. On the other hand, the antiphlogistians asserted, that no change was thus made upon it, farther than adding a quantity of pure air, which they suppose to be the basis of all acids. On this subject, however, M. Cornette maintains, that the marine acid seems to have so little action upon inflammable substances, merely because it is weaker than the rest; and likewise that it is often previously combined with some inflammable matter, by which its attraction is prevented. He maintains, that if the marine acid be concentrated in such a manner as to render its specific gravity to that of water as 19 to 16, it will then act upon oils with heat and effervescence, reducing them to a black and thick substance, and even burning them to a kind of coal. Some experiments have been made by Mr Haffe,

with a view to investigate the action of the marine and vitriolic acids upon balsams and oils; for which purpose he mixed two drachms of smoking spirit of salt with one of each of the oily substances to be tried. The results were, that Canada balsam gained one scruple in weight; balsam of capivi 19 grains; storax, and Venice turpentine, each one scruple; asphaltum 18 grains; but the essential oils of anise-seed, benzoin, bergamot, coriander, and many others, were not altered in any degree. The action of this acid upon inflammable matters, however, is augmented by its being reduced into the form of air.

Gmelin relates, that, by distilling a mixture of five parts of salt, twelve of spirit of wine, and four of vitriolic acid, to which he had previously added one or two parts of water, he obtained a completely dulcified spirit of salt, and an imperfectly dulcified spirit of vitriol, upon rectifying the liquor.

Homburg found, that glass was corroded by the marine acid: and his observation has been confirmed by Dr Priestley; who finds that its corrosive power is augmented by confining the acid in tubes hermetically sealed. Its power is exerted not only on flint-glass, but even on common green glass; though more powerfully on the former, where it chiefly attacks the red-lead used in its composition. By inclosing marine acid gas for some weeks in a glass tube exposed to heat, an incrustation was formed on the inside, while the air was diminished to $\frac{1}{8}$ of its original bulk, one half of which was absorbed by water; the other was phlogisticated air.

1482

Glass cor-
roded by it.

The marine acid is generally met with of a yellow or reddish colour, which by Macquer is given as one of its characteristic marks. In general, however, this colour is thought to proceed from iron; but Dr Priestley has found that it may be produced by many different substances; and his observations have been confirmed by Scheele and other chemists. The Doctor is of opinion that it is occasioned for the most part, if not always, by a mixture of earth; and he was able to communicate it by means of calcined oyster-shells, calcined magnesia, pipe-clay, or pounded glass; but not by wood-ashes, from whence the air had been expelled by heat. It was effectually discharged by flowers of zinc, a coal of cream of tartar, and by liver of sulphur; but he found, that the colour which had been discharged by liver of sulphur, would return by mere exposure of the acid to the atmosphere, but not that which had been discharged by flowers of zinc.

acid.

Dephlogisticated Spirit of Salt.

When the action of this vapour upon any thing is to be examined, the substance must be put into a bottle in such a manner as to remain in contact with it; or it may be put into a glass tube, which is suspended and fixed to the stopper, and thus introduced into the bottle. From its property of destroying all vegetable colours, it promises to be of very considerable use in the arts, provided it could be had in sufficient quantity, and cheap. It bleaches yellow wax, and when properly applied to linen, will whiten it sufficiently, and without injury, in a few hours. This may be effected by steeping the linen for that space of time in water impregnated with the dephlogisticated marine gas. It unites with this fluid rather more easily than fixed air.

1484

Expedition
method of
bleaching
linen.

Ber-

Marine Acid Berthollet, in order to impregnate water with it without exposing the operator to the fume, which is extremely disagreeable, put the mixture of marine acid and manganese into a retort. To this he applied first an empty bottle, and then several others filled with water, and communicating with each other by means of bent tubes; surrounding the whole with ice. When the water in the bottles was saturated, the gas became concrete, and fell to the bottom; but with the smallest heat it arose to the top in bubbles. The specific gravity of the saturated water was to that of distilled water, when the thermometer was only five degrees above the freezing point, as 1003 to 1000. This impregnated water is not acid, but has an austere taste, and has the same action as the gas, though in a weaker degree. Mr Berthollet has observed, that the addition of alkalies does not prevent, but rather promotes, the discharge of colours; for which reason he directs to add a fixed alkali to the impregnated water in which linen is to be steeped for bleaching. This is the expeditious method hinted at under the article BLEACHING; but which has not hitherto come into use, principally through the high price of the dephlogisticated gas.

The dephlogisticated marine acid does not discharge all colours with equal ease. Those of litmus and syrup of violets are entirely destroyed, and turned white. The colouring matter of Brazil-wood, and some green parts of plants, retain a yellow tint. The leaves of evergreen plants resist its action for a long time, and at last only acquire the yellow colour which they assume by long exposure to the air; and in general the changes of colour which vegetable matters suffer from this gas, are similar to those which take place on long exposure to the air; and by this operation the gas is converted into common marine acid.

1485 **Effect of the dephlogisticated acid on phlogistic matter, &c.** Oils and animal fats are thickened by this gas; and by these and other inflammable substances it is reduced to the state of common marine acid. Light is said to produce the same effect. It unites with fixed alkalies and calcareous earths, but without any sensible effervescence; and thus they lose their peculiar taste and colour. M. Berthollet having boiled in a retort, to which a pneumatic apparatus was affixed, some of the dephlogisticated marine acid liquor with mineral alkali, thus obtained a considerable quantity of elastic fluid, composed partly of fixed air, partly of the air contained in the vessels, and partly of air considerably purer than that of the atmosphere. The result of the combination was common salt. On repeating the experiment with lime, no fixed air was obtained; but that which came over became gradually more and more dephlogisticated. Volatile alkali, even when caustic, occasioned an effervescence, and emitted a peculiar kind of air, which was neither fixed nor dephlogisticated, but of a peculiar kind.

Green vitriol is changed to a red by the dephlogisticated gas, but the colour of blue and white vitriols is not affected. By the assistance of light, it acts upon phosphorus, and the result is phosphoric and common marine acids. It does not dissolve ice nor camphor; in which respects it differs from the common marine acid gas.

1486 **Marine ether.** On mixing marine acid, manganese, and spirit of wine, and distilling them with a very gentle heat, little

air of any kind is produced, but a quantity of ethereal liquor very slightly acid. The proportions used by Pelletier were an ounce and a half of manganese, five ounces of concentrated marine acid, and three ounces of spirit of wine. "In this process (says Mr Keir), the whole of the dephlogisticated acid seems to have united with the spirit of wine, and to have formed ether. The difficulty of combining marine acid with spirit of wine, so as to form an ether, is well known; and though there have been some approximations to it, yet the only instances in which it has been completely effected, have succeeded in consequence of the marine acid being dephlogisticated; by which its action on spirit of wine, as well as on all inflammable matters, is greatly increased."

M. Pelletier has observed, that when we put a bit of phosphorus into dephlogisticated marine gas, the former is immediately dissolved, and a light is perceived, the vessel being filled at the same time with white vapours. He has likewise observed, that sea-salt, with an excess of pure air, thrown into heated vitriolic acid, produces a small detonation. To make this salt in quantity, take, for instance, ten pounds of sea-salt, mixing it with from three to four pounds of manganese, pour on the mixture ten pounds of vitriolic acid, and distil with Woulfe's apparatus. Pass the disengaged acid through a solution of fixed vegetable alkali, either caustic or otherwise. A little more than ten ounces of the new marine salt with excess of pure air is obtained, and a quantity of salt of Sylvius, or digestive salt. The salt with excess of pure air crystallizes first, and by means of repeated crystallizations, is entirely disengaged from the other.

V. AQUA REGIA.

1487 **Method of procuring a detonating salt from the acid in quantity.** This acid, which is named from its property of dissolving gold, is compounded of the nitrous and marine acids. Gold and platina cannot be dissolved in any other menstruum, nor can regulus of antimony and tin be so easily dissolved by any other as aqua regia. It may be made in various ways. 1. By adding the two acids to each other directly. 2. By dissolving in the nitrous acid some salt containing marine acid, particularly sal ammoniac and common salt. 3. By distilling nitrous acid from either of these salts. And, 4. In Dr Priestley's method of impregnating marine acid with nitrous acid vapour.

The only difference between those liquors prepared by the methods above mentioned is, that when sal ammoniac or sea-salt are dissolved in the nitrous acid, the aqua-regia contains a quantity of cubic nitre, or nitrous ammoniac, which, tho' it cannot much affect the acid as a solvent, may make a considerable difference in the nature of the precipitate. Thus, gold precipitated from an aqua-regia formed by the pure nitrous and marine acids, does not fulminate, though it does so when precipitated from one made with sal ammoniac. There are no established rules with regard to the proportions of nitrous and marine acids, or of nitrous acid and sal ammoniac, which ought to be employed for the preparation of aqua-regia. The common aqua-regia is made by dissolving four ounces of sal ammoniac in 16 ounces of nitrous acid; but these proportions must be varied, according to the nature of the intended solution.

Borax.

tion. Platina, for instance, is dissolved in the greatest quantity by equal parts of the two acids; regulus of antimony by four parts of nitrous acid to one of marine; and, in general, the greater the quantity of marine acid employed in the mixture, the less are the imperfect metals, particularly tin, calcined or precipitated by it. A mixture of two parts of spirit of nitre, and one of spirit of salt, dissolves nearly an equal weight of tin into a clear liquor, without forming any precipitate; but, for this purpose, the operation must be conducted slowly, and heat avoided as much as possible.

VI. BORAX.

1490
Methods of
purifying
borax.

IN a memoir in Crell's Chemical Annals, by M. Tychson, the author shows, by different experiments, that it may sometimes be purified by solution, filtration, and evaporation only; but that sometimes the operation is more easy and effectual by previous calcination; but then the product is a little lessened, especially if the calcined mass be not well powdered, and then boiled sufficiently in water. Powder of charcoal, he says, may be sometimes advantageously employed in the purification; but in general there is no difference between the crude and purified borax, except in the addition of extraneous matters; at least, as the quantity of acid is the same, the addition of mineral alkali is useless: these extraneous matters are an animal fat, and a sand composed of clay, lime, and a martial earth. If the oily matter of tartar be separated by passing the lixivium through a stratum of clay, as is supposed in the preparation of the crystals at Montpellier, it would suggest a method of greatly abridging the process of the purification of borax.

VII. ACID of BORAX, or SEDATIVE SALT.

1491
Method of
preparing
the sedative
salt from
borax.

ON the preparation of this salt Mr Beaumé observes, that a little more acid ought to be added to the borax than what is just sufficient to saturate its alkaline basis. Unless this be done, the sedative salt remains confounded with the other saline matters in the solution, and of consequence the crystallization must be disturbed. The salt, though formed in an acidulated liquor, is easily deprived of its superfluous acid by draining upon paper. It does not crystallize as soon as the stronger acid separates it from its basis, even tho' the solution of borax had been previously made as strong as possible; but this delay is occasioned by the heat of the liquor; for as soon as it cools, a considerable quantity of crystals is formed.

1492
Its proper-
ties.

The acid of borax does not fall into powder when exposed to the air, but rather attracts a little moisture from it. Its taste is at first somewhat sourish, then cooling and bitterish; and lastly, it leaves an agreeable sweetness on the tongue. It makes a creaking sound, and feels a little rough between the teeth; and when vitriolic acid is poured upon it, exhales a transient odour of musk. It is soluble, according to some chemists, in the proportion of one to 20 in cold water, or of one to eight in boiling water. Wenzel informs us, that 960 grains of boiling water dissolve 434 of the salt; while, on the other hand, Morveau asserts, that he could dissolve no more than 183 grains in a pound

of distilled water. Rouss informs us, that fixed air prevents the solution of the salt in water; and Morveau, that its solubility is much augmented by cream of tartar. When previously made red hot, it dissolves in water with a smell of saffron, and a grey powder of an earthy appearance is precipitated, which is soluble in vitriolic and marine acids, and may be again precipitated in the form of sedative salt.

Phlogisticated alkali makes no change on sedative salt in solution; but paper dipped in a solution of it in vinegar, and afterwards dried, burns with a green flame. It is capable of vitrification, though mixed with fine powder of charcoal; and with foot unites into a black mass like bitumen; which, however, is easily soluble in water, and can scarce be reduced to ashes, but partly sublimes. By the assistance of heat it dissolves in oils, especially those of the mineral kind; and with these it yields solid and fluid compounds, which give a green colour to spirit of wine. Rubbed with phosphorus it does not prevent its inflammation; but a yellow earthy matter is left behind. It seems also to give to white and red arsenic a great degree of fixity, so as even to become vitrescible in the fire; and this property it communicates also to cinnabar. When mixed and heated with powder of charcoal, it forms no liver of sulphur.

Sedative Salt COMBINED.

1. *With volatile alkali.* The produce of this is a peculiar ammoniacal salt, which does not evaporate when thrown on burning coals, or otherwise intensely heated, but melts into glass of a greyish colour, but transparent, which cracks when exposed to the air; and, on dissolution in water, shoots into small crystals, which appear to have lost none of their alkaline basis. It may be decomposed by the acetous as well as the mineral acids, and by fixed alkalies and lime.

2. *With magnesia* this acid shoots into irregular crystalline grains soluble in vinegar and acid of ants; in which liquids they crystallize like small needles joined together at right angles. They are decomposed by all other acids, and likewise by spirit of wine. In the fire, however, they melt easily without any decomposition; and in the dry way sedative salt decomposes all the earthy salts formed by magnesia and any of the volatile acids.

3. *With pure earth of alum*, sedative salt forms a salt very difficult of solution, when one part of earth is ground with four times its weight of sedative salt and water. The same kind of earth, mixed with half its weight of sedative salt, forms a hard grey mass, resembling pumice stone; part of which is soluble in water, and yields a mealy sediment, together with some sedative salt unchanged.

4. *With siliceous earth* the sedative salt does not unite in the moist way; but, on melting one part of acid with two of this earth, we obtain a frothy, hard, greyish-white mass, from which, however, the acid may be again procured.

5. *Gold* is not acted upon in the wet way by acid of borax; nevertheless Rouss observed, that when sedative salt was melted with gold-leaf, it did not vitrify, but became frothy and hard, did not colour the flame of spirit of wine, and only a little of it was soluble in water in which sedative salt had been crystallized.

A

Acid of Bo-
rax and its
Combina-
tions.

A solution of borax in which sedative salt was dissolved, did not precipitate gold.

6. *Platina* is not precipitated from aqua regia by sedative salt.

7. *Silver* is not affected by melting with an equal quantity of sedative salt; but the latter is vitrified in such a manner as to become insoluble in water.

8. *Mercury* is not dissolved either in the dry or wet way; but a solution of borax saturated with sedative salt precipitates it in a yellow powder from nitrous acid.

9. *With copper.* On this metal sedative salt acts but weakly, even when the solution is boiling hot; nevertheless, as much of the metal is dissolved, as gives a little white precipitate on the addition of fixed alkali; but volatile alkali does not throw down a blue precipitate, nor turn the solution of that colour. The solution of borax precipitates all solutions of copper in acids, and then the sedative salt unites with the copper in form of a light green jelly, which, after drying, is of very difficult solution in water. Bergman says, it is of an agreeable green colour, which it preserves after being dried; and that, when exposed to the fire, it melts into a dark-red vitreous substance. Wenzel asserts, that by long continued trituration of copper filings with sedative salt he obtained a solution of the metal, which yielded crystals on being evaporated. With twice its weight of copper in a covered crucible, an insoluble vitreous mass was obtained.

10. *Tin* is not apparently acted upon by boiling with sedative salt; nevertheless, the solution becomes turbid on the addition of an alkali. By melting the calx with half its weight of sedative salt, we obtain a black mass like the dark coloured tin ore. By rubbing for a long time filings of tin with sedative salt and water, and afterwards digesting the mixture with heat for one day, an hard, sandy, and irregularly shaped salt was obtained, which, by dissolution in water, yielded transparent, white, polygonous crystals; and a salt of the same kind was obtained from the slag produced by melting equal parts of sedative salt and tin filings.

11. *Lead* is not acted upon directly; but, on adding a solution of borax to solutions of the metal in vitriolic, nitrous, marine, or acetic acids, the sedative salt unites with the lead. One part of sedative salt with two of minium gives a fine, greenish-yellow, transparent, and insoluble glass.

12. *With iron.* The acid of borax dissolves this metal more easily than any other. The solution is amber-coloured, and yields an ochry sediment, with clusters of yellow crystals containing a little iron. The metal is precipitated by borax from its solutions in vitriolic, nitrous, marine, and acetic acids, and the precipitates are soluble in sedative salt. A solution of iron may also be obtained by melting this salt with iron filings, and lixiviating the mass.

13. *Zinc* communicates a milky colour by digestion with solution of sedative salt. By evaporation it affords a confused saline mass, and a white earthy powder by precipitation with alkali. Flowers of zinc, melted with sedative salt, form a light green insoluble slag.

14. *Bismuth*, in its metallic state, is not acted upon by sedative salt, but is precipitated by borax from a mix-

ture of vitriolic and marine acids, in form of a very white powder, which keeps its colour when exposed to air, and melts in the fire to a white, transparent, and permanent glass.

15. *Regulus of antimony* is not acted upon directly, but its calx is dissolved when precipitated by borax from a solution in aqua regia.

16. *White arsenic* unites with sedative salt either in the dry or moist way, and forms a crystallizable compound, forming either pointed ramifications, or a white, greyish, and yellowish saline powder.

16. *On regulus of cobalt* the acid has no direct action; but borax precipitates it from its solution, and the calx melts with the salt into a slag of a bluish-grey colour; and this, by lixiviation and evaporation, affords a sedative salt impregnated with cobalt, of a reddish white colour, and of a ramified form.

18. *Nickel* is precipitated from its solution, and the sedative salt unites with it into a saline substance difficult of solution.

A variety of opinions have been formed concerning the nature of sedative salt. M. Beaumé and M. Cadet particularly have made a great number of experiments on the subject; but as none of these have led to any certain conclusion, we forbear to mention them at present. Those of Messrs Exchaquet and Struve have indeed established some kind of relation between the acids of borax and phosphorus, and they have made several attempts to analyze the former, but with little success. The most remarkable of these experiments are the following. 1. They distilled, with a strong heat, two parts of phosphoric acid evaporated to the consistence of honey, one of sedative salt, and two of water. Towards the end of the distillation a very acid liquor was obtained; and the residuum was a white earth, in quantity above three-fourths of the sedative salt employed, and which, on examination, was found to be the siliceous earth; the liquor which passed over into the receiver being found to be the volatile phosphoric acid. If, in this experiment, too much phosphoric acid be added, a greasy matter remains; and, if too little, a part of the sedative salt will remain undecomposed. In their attempts to compose borax, they combined phosphoric acid with mineral alkali, the result of which was a compound resembling borax in many respects. When exposed to the fire, it melts into a very fusible glass, which has a mild taste, and seems neutral, but, on exposure to the air, becomes moist and acid. On being saturated with alkali a second time and vitrified, it again deliquesces and becomes acid; and the more frequently this operation is repeated, the greater is the resemblance it bears to borax. In this experiment they supposed that the alkali was decomposed, and converted into an earth similar to that of sedative salt.

With earthy substances the results were very remarkable. With earth of alum a crystallizable salt was obtained, which made paper burn with a green flame. Fixed alkali added to a solution of this salt precipitates an earth, and the salt then formed by crystallization resembles borax in several properties.—In the dry way the earth of alum, with the phosphoric acid, melts into a glass of the same fusibility as that of borax, and like it is fixed in the fire. The solution of this glass did not crystallize. Common clay.

1493
Experiments made to determine the nature of the sedative salt.

Acid of
Amber.

clay digested with phosphoric acid produces silky crystals resembling sedative salt. When dried with their mother-water, these give a clear glass, which, when united with mineral alkali, has the taste of borax, smells in the same manner, and has the same effect upon metals. With lime, magnesia, and terra ponderosa, this acid produces fusible glasses, insoluble in water, and which communicate a green colour to flame. Earth of bones and selenite mixed with the acid gave a white, hard, shining glass, like the best crystal, but as fusible as the glass of borax, and which continued flexible after it had ceased to be red-hot. Two parts of gypsum, with one of phosphoric acid, gave a milk-white glass fit for soldering metals and enameling. In these experiments, however, it must be remembered, that unless the heat be raised very quickly, the phosphoric acid will be evaporated before any fusion takes place.

VIII. *ACID OF AMBER.*

It was known to Agricola, that a particular kind of salt could be obtained from amber by distillation; but neither he, nor any succeeding chemist for some time, ascertained its acid properties. On the contrary, some erred so far as to imagine that it was a volatile alkali; but, about the beginning of the present century, its acidity began to be generally acknowledged. This property indeed discovers itself by the taste, which is manifestly acid and empyreumatic, along with the peculiar flavour of amber. According to Scheele, also, the aqueous fluid which passes over in the distillation of amber, is an acid resembling vinegar both in taste and chemical properties; and which of consequence ought not to be confounded with the true acid of amber, which manifests qualities of a very different kind.

1494
Methods
of purifying
the salt of
amber.

The properties of salt of amber can hardly be investigated until it has been purified; for which, of consequence, various methods have been proposed. Pott recommends crystallization, after having filtered the solution through cotton-wool, in order to retain the oil. Cartheuser attempts the purification by dissolving the impure salt in spirit of wine, then diluting with six times its quantity of water, and crystallizing the salt. Others recommend sublimation with common salt or sand, and Bergman with pure clay.

The salt of amber dissolves, by the assistance of heat, in nitrous and marine acids, and in the vitriolic without heat. In none of these combinations, however, does it either alter the dissolving acids, or suffer any alteration itself, except that it becomes whiter; with nitre it detonates and flies off; and if the quantity of salt of amber has been greater than that of nitre, the latter is alkalized. Stockar informs us, that it expels the marine acid from sal ammoniac, and sublimes before that salt; with which it does not form any union. When sublimed from common salt, it does not alter the latter in any other respect than giving it a darker colour. It precipitates calcareous earth from its solution in vinegar; and it decomposes sugar of lead; but the precipitate differs from plumbum corneum. It does not prevent the solution of lead in the acids sea-salt and nitre; nor does it produce any sulphureous smell by calcination with charcoal. Hence it appears that it is neither a vitriolic, nitrous, nor marine acid; and M. Bourde-

lin must have been mistaken, when he affirms, that, after detonation of this salt with nitre, he obtained a residuum, which tasted like common salt, decrepitated in the fire, yielded crystals of a cubical form, precipitated silver and mercury from the nitrous acid; and thence concluded that it was the same with acid of sea-salt. It is very dear, as only about half an ounce can be obtained from a pound of amber.

Acid of Amber COMBINED,

1. *With fixed vegetable alkali.* By saturating salt of amber with the fixed vegetable alkali, and then slowly evaporating the solution, we obtain, according to Wenzel, a light deliquescent saline mass; but, according to Stockar, whose experiments are confirmed by those of Mr Keir, the solution above mentioned affords shining white transparent crystals of a triangular prismatic figure, with the terminating points truncated. These crystals readily dissolve in water, deliquesce in the air, and have a peculiarly bitter saline taste. In the fire they decrepitate, melt, and remain neutral; though Wenzel has observed, that with an intense heat they are decomposed and become alkaline. These crystals do not change aquafortis into aqua-regia; and though they precipitate both the solutions of lead and silver, the precipitates are neither plumbum corneum nor luna cornea.

2. *With mineral alkali.* This combination produces long three-sided columnar crystals, intermixed with some that are foliated. These crystals do not deliquesce in the air, and have a saline, bitter, and smoky taste. They are less soluble than common salt, and melt with more difficulty than nitre. They do not become alkaline on burning coals, and, in their other properties, resemble the former.

3. *With volatile alkali.* This salt shoots into acicular crystals, having a sharp, saline, bitter, and cooling taste; when heated in a silver spoon, they melt and evaporate entirely; in close vessels they sublime. They do not precipitate solution of silver, nor change spirit of nitre into aqua-regis. A powerful antispasmodic remedy is prepared from rectified spirit of hartshorn and salt of amber.

4. *With lime.* This shoots into oblong pointed crystals, which do not deliquesce in the air, and are soluble with difficulty even in boiling water; nor, according to Mr Stockar de Neuforn, can they be decomposed by distillation either with acetous or marine acids. They detonate by distillation with nitrous acid; and are decomposed, either in the moist or dry way, by the vitriolic. When mixed with common sal ammoniac in the dry way, they suffer a decomposition; the succinated ammoniacal salt flying off, and the combination of marine acid with lime remaining behind.

5. *With magnesia.* This yields a white, gummy, frothy, saline mass, which acquires a yellowish colour when dried by the fire; and, when cool, deliquesces in the air. It is decomposed by alkalies and lime, as well as by the vitriolic acid.

6. *With clay.* By uniting the acid of amber with an edulcorated precipitate of alum with vegetable alkali, Wenzel obtained prismatic crystals, which could not be decomposed by alkalies.

7. *With silver.* The acid of amber has no effect on silver

Acid of
Amber and
its Combi-
nations.

Acid of Amber and its Combinations. silver in its metallic state; but with its precipitate forms thin oblong crystals, radiated and accumulated upon one another, from which the silver may be separated by alkalies, by quicksilver, and by copper.

8. *With copper.* By a long digestion of copper with acid of amber a green solution is obtained, which by mixture with common salt is rendered turbid, by vitriolic acid white, and lets fall a green precipitate on the addition of fixed alkali. Wenzel, however, could not obtain this precipitation by alkalies. His solution yielded groups of green crystals, gave a crust of copper to zinc, and was precipitated by liver of sulphur.

9. *With iron.* Wenzel dissolved a precipitate of this metal in acid of amber, and from the solution obtained small, brown, transparent, and stellated crystals. Zinc precipitated the metal, but not alkalies. From a slightly coloured solution of metallic iron, Pott obtained, by means of alkali, a white precipitate, which soon became yellow, and at length green, by pouring water upon it.

10. *With tin.* Acid of amber dissolves tin when precipitated by a fixed alkali; and the solution yields thin, broad, and foliated transparent crystals. Alkalies throw down but little from this solution; liver of sulphur more; and lead, iron, or zinc, nothing.

11. *With lead.* Acid of amber whitens the surface of lead in its metallic state, but does not dissolve it; neither can lead be precipitated from its solutions in nitrous and marine acids by salt of amber, though this is denied by Pott. According to Stockar, however, it forms a white precipitate with sugar of lead. This metal precipitated by an alkali, and dissolved in acid of amber, forms long foliated crystals lying upon one another; from the solution of which the lead may be precipitated by alkalies in the form of a grey powder, and by zinc in its metallic state.

12. *Zinc,* in its metallic state, is readily dissolved by the acid of amber; and by a combination with the precipitate formed by fixed alkali, we obtain long, slender, foliated crystals, lying upon one another. The solution lets fall a white precipitate on the addition of fixed alkali; but this is denied by Stockar, who says that volatile alkali produces a red precipitate.

13. *Bismuth.* By means of heat, Stockar obtained a solution of this semimetal in acid of amber, which was decomposed by alkalies. Wenzel obtained, from a precipitate of bismuth prepared by means of fixed alkali, small, slender, foliated, and yellow crystals; which alkalies cannot decompose, though black precipitates are thrown down by lead and zinc.

14. *Regulus of antimony.* Little or none of this semimetal, in its reguline form, is dissolved in the acid of amber; but it attacks the precipitate made with fixed alkali. This solution is very copiously precipitated by liver of sulphur, but not by alkalies.

The combinations of this acid with gold, platina, nickel, arsenic, and manganese, have either been found impracticable, or not yet attempted; all those above described are non-deliquescent, and part with their acid when exposed to fire. The elective attractions of this acid, according to Bergman, are singular, as it adheres more strongly, not only to terra ponderosa and lime, but to magnesia, than to fixed alkali.

On the origin of salt of amber, Mr Keir remarks, that "it deserves to be considered as a pure and di-

stinct acid. No proofs have been adduced of its being a modification either of the marine or vegetable acids, as Mr Cornette and M. Hermbstadt have supposed. The former, having distilled spirit of salt with oil of lavender, obtained an acid which smelled like salt of amber, but on examination was found to retain the properties of the muriatic acid. He also relates, that, when purifying a considerable quantity of the salt of amber which he had prepared himself, some sea-salt was separated, which in the distillation had arisen along with it. But this observation cannot be justly applied to show any resemblance betwixt these two, any more than the smell in the former case could show an analogy betwixt it and oil of lavender. This mixture of sea-salt with acid of amber, however, may readily explain the mistake of M. Bourdelin already mentioned. M. Westrumb and M. Hermbstadt have both laboured in vain to convert the acid of amber into acids of sugar and tartar by frequent distillations with spirit of nitre; and their want of success confirms the account already given, that the acids of nitre and amber have no action upon each other, farther than that the former is phlogisticated or changed into red fumes, and the latter becomes whiter. Nevertheless, if Mr Scheele's observation of the identity of the acid liquor, which comes over in the distillation of amber with acetous acid, holds good, we shall have the best reason yet given to ascribe the origin of this acid to the vegetable kingdom; and when we consider the very different properties that are assumed by the vegetable acids, which, however, are convertible into one another, no reason can be drawn from the diversity of its properties with those of other vegetable acids, against its having a common origin with them. Indeed the natural history of amber, its similarity to gums and resins, and its involved insects, afford other arguments in favour of the opinion.

IX. Acid of ARSENIC.

M. Berthollet remarks upon Mr Scheele's process, that during the operation a great quantity of dephlogisticated air is expelled from the acid. M. Pelletier has found another method of procuring the arsenical acid. He mixes common white arsenic with nitrous ammoniac, and distils the mixture. At first phlogisticated nitrous acid passes over, then the volatile alkali, and lastly the arsenical acid remains in the retort in form of a vitreous mass, which deliquesces into a very dense acid liquor, reddening syrup of violets, and effervescing with alkalies. M. Macquer had formerly described this process, and observed, that the nitrous acid passes over first, and then the volatile alkali; but was of opinion that the residuum was nothing but arsenic. He mentions a detonation which took place in his experiment; but nothing of this kind was observed by M. Pelletier: he only informs us, that the nitrous acid was driven over with great violence, while that of arsenic united with the volatile alkali. M. Berthollet, who has endeavoured to ascertain the weight gained by the conversion of sulphur, phosphorus, and arsenic, into acids, determines that of arsenic to be about one-ninth of the whole. At the same time he observes, that this additional weight does not discover the whole weight of the air contained in the

Acid of Amber and its Combinations. 1495 On the nature of the acid of amber.

1496 M. Pelletier's method of procuring the arsenical acid.

Acid of Molybdæna.

the arsenic, as it had that necessary to convert it into calx before the operation of converting it into an acid was begun. On the other hand, M. Bergman asserts, that one-fifth of white arsenic is phlogiston, and that this calx is converted into acid merely by being deprived of its phlogiston. Thus the *facts* related by these two celebrated chemists differ enormously from one another; M. Berthollet affirming that the arsenic *gains* a ninth of its original weight in the process of acidification; and M. Bergman, that it *loses* a fifth part of the same. M. Berthollet endeavours to reconcile this, by supposing that Bergman had employed marine acid for the preparation of his arsenical acid, which is well known to carry off with it some part of most of those substances with which it is capable of combining; and to this he attributes the loss of weight in Bergman's process.

IX. ACID OF MOLYBDÆNA.

1497
M. Pelletier's experiments.

THE opinion of M. Bergman concerning the metallic nature of the acid of molybdæna has obtained some confirmation from the experiments of M. Pelletier. He was not able indeed to obtain any regulus; but by means of oil alone he procured, by two hours vehement heat, a substance slightly agglutinated with a metallic lustre, containing small round grains of a grey metallic colour, very visible by the help of a magnifier. These he supposes to have been a true regulus of molybdæna; which he found to possess the following properties. 1. It is calcinable by fire into white calx. 2. It detonates with nitre, and the residuum is a calx of molybdæna united with the alkali of the nitre. 3. It is converted into a white calx by means of nitrous acid. 4. It yields inflammable air when treated with alkalis in the dry way, and forms peculiar compounds with them. 5. It forms regenerated molybdæna with sulphur. 6. It unites, and forms peculiar substances with metals. By uniting it with silver, iron, and copper, we have friable reguline masses; and refractory powders with lead and tin.

Our author, in consequence of his experiments, considers molybdæna as a metallic substance mineralized by sulphur; and the earth called the acid of molybdæna as a calx much dephlogisticated, which has retained part of the air contained in the nitrous acid. He observes likewise an analogy betwixt molybdæna and antimony in their chemical results. Both of them yield vitrifiable argentine flowers by similar operations, and both are changed into white earths by nitrous acid; but they differ in the two following respects. 1. The latter easily gives a fusible regulus; but the molybdæna seems to be the most refractory of all the femimetals. 2. The calx of regulus of antimony is soluble by alkalis in the moist way, but that of molybdæna is not.

X. ACID OF TUNGSTEN OR WOLFRAM.

1498
Properties of tungsten.

MR LUYART, who has examined this mineral, gives the following account of it. 1. It is infusible by the blow-pipe, though the angles of the pieces into which it is broken are thereby rounded. 2. It effervesces with microcosmic salt, and melts before the blow-pipe into a reddish glass. 3. With borax it effervesces;

N^o 75.

and by the outward flame of the blow pipe is changed into a reddish glass; by the internal flame into a greenish one. 4. Heated by itself in a crucible, it swelled, became spongy, semivitrified, and was attracted by the magnet. 5. With an equal part of nitre it detonated, or boiled up with a blue flame round the edges, and nitrous vapours arose. The mass was soluble in water, and let fall a white precipitate with acid. 5. It melted readily with fixed alkali, leaving a kind of black matter in the crucible, and a smaller quantity of lighter coloured substance on the filter. These residuums showed a mixture of iron and manganese. 6. With nitrous acid the filtered solution let fall a white precipitate, at first sweet, but afterwards bitterish and sharp, and which caused a disagreeable sensation in the throat; and the acidity of the solution of it was manifest, by its turning the tincture of turnsole red.

Having examined the substance by means of liquids in Mr Scheele's way, they obtained the same yellow powder which he had characterized as the acid of tungsten, along with a very small residuum, which appeared to contain a mixture of tin. Proceeding farther in the analysis, they found that wolfram is composed of manganese, calx of iron, the yellow matter called the *acid of tungsten* by Bergman and Scheele, with a very little mixture of quartz and tin, and which they considered as accidental.

1499
Of the yellow matter, called its acid by Mr Scheele.

They now proceeded to examine the yellow matter, supposed by the two celebrated chemists just mentioned to be a simple acid salt, but which turned out very different on their inquiries. In order to procure a quantity of it, they melted six ounces of wolfram with as much vegetable alkali, dissolved the mixture in distilled water, filtrated the liquor, and evaporated it to dryness. Thus they obtained a white salt; upon which, when dry, they poured nitrous acid, and set it to boil in a sand-bath; by which operation it became yellow. They then decanted the liquor, pouring fresh acid upon the residuum; and repeated the operation a third time in order to deprive it of all the alkali. The remaining powder was then calcined in a cupelling furnace under a muffle, when it came out quite pure and yellow. The properties of it were then found to be as follow. 1. It is entirely insipid, and of the specific gravity of 6.12. 2. Before the blow-pipe, it continues yellow in the exterior flame even though put on charcoal; but grows black and swells, though it does not melt, in the internal flame. 3. In the internal flame it forms a blue transparent glass with microcosmic salt. The colour vanishes in the external flame, but appears again in the internal one; but by a continuance of this operation, it at last loses its colour so much that it cannot be recovered. 4. It effervesces, and forms a brownish yellow transparent glass with borax, which keeps its colour in both flames. 6. When triturated with water, it forms an emulsion which passes through filters without becoming clear, and continues a long time without any deposition. 7. It is insoluble in acids, but dissolves readily in the vegetable alkali both in the moist and dry way; though the produce has always an excess of alkali. 8. On adding nitrous acid in greater quantity than what is necessary to saturate this excess, a white powder falls, which is the same with the acid of tungsten discovered by Mr Scheele; but which Messrs Luyarts will not

Acid of Tungsten.
1500
No simple acid procurable from tungsten.

not allow to be a simple acid, though they admit that it contains one; and affirm, that its properties are various according to the circumstances of its precipitation. The properties of it, as described by them, are the following. 1. It is fusible before the blow-pipe, exhibiting the same phenomena as the yellow matter. 2. By calcination in a little pot or test, it emits the smell of nitrous acid, and turns yellow; but, on cooling, remains white, insipid, and insoluble; and this residuum melts by itself before the blow-pipe. 3. A yellow colour is produced either by vitriolic or marine acids; and the filtrated liquor affords a neutral salt with basis of fixed alkali, according to the nature of the acid employed. If the vitriolic acid is employed, and the operation performed in a retort, a quantity of nitrous acid passes over. 4. If, instead of pouring the acid on the salt, it be poured upon its solution, no precipitate will be formed, not even by making the liquor boil, if the quantity of acid is small; only the solution loses its sweet taste, and acquires more bitterness. On pouring on a large quantity of acid, and causing the liquor boil, a yellow precipitate is formed in every respect similar to the yellow matter so often mentioned. 5. This salt is completely dissolved by boiling with vinegar. On leaving the solution to cool, a white waxy matter adheres to the sides of the vessel; which being washed and kneaded with the fingers, forms an adhesive mass like bird-lime, having a fat and greasy taste. By exposure to the air it acquires a dark grey colour, loses its adhesive property, and becomes bitter. It dissolves in water; and gives it first a sweet, then a bitter taste, making the tincture of turnsole red. 6. On evaporating the alkaline solution to dryness, pouring acetous acid upon the residuum, and then making it boil, the greater part of the residuum was dissolved, and on cooling afforded feathery crystals. These when edulcorated had a sweet taste, though less strong than that of the former salt, which afterwards became bitter. Their solution turned blue paper red; was precipitated, and became like an emulsion with spirit of wine; and the residuum, which did not dissolve, appeared to be of the same nature. The crystals dissolved in fresh acetous acid, and communicated a blue colour to the acid; but this gradually disappeared on cooling, and a glutinous matter was deposited on the sides of the vessel, which had the properties of the former substance of that sort. If, in place of letting the solution cool, it should be kept boiling, the blue colour disappears, and nothing is precipitated. By adding spirit of wine when the liquor is almost evaporated to dryness, a white powder is precipitated; which, after being edulcorated with fresh spirit of wine, tastes exceedingly bitter, and is very soluble in water. This solution, however, does not redden blue paper, nor make a blue with vinegar. With vitriolic acid its solution is blue; with vitriol of copper it forms a white precipitate. All these salts, by calcination, first become blue, then yellow, and lastly white. 7. On pouring a quantity of lime-water upon the solution of the precipitate formed by the nitrous acid, as well as on those obtained by the acetous acid, white precipitates were formed, all of which were a true regenerated tungsten. Having afterwards impregnated the liquors with fixed air, and boiled them in order to precipitate the lime more completely, they found in the

VOL. IV. Part II.

solutions, after they were filtrated and evaporated to dryness, neutral salts formed of the precipitating acids, joined with alkaline and calcareous bases. This proved, that both alkali and acid were concerned in the precipitation. 8. On pouring the vitriolic solutions of iron, copper, and zinc, as well as that of marine mercurial salt, alum, and Prussian alkali, upon the solution of the precipitate formed by the nitrous acid, no precipitation ensues, and the acetous salts of copper and lead give white precipitates; but the Prussian alkali forms no precipitate with the acetous salts. Hence it appears, that this salt is not a simple acid, but rather a salt composed of the yellow matter, fixed alkali, and the precipitating acid; and its composition appears more fully from the following experiments with the volatile alkali.

1. The yellow powder dissolves entirely in volatile alkali, but without any perfect saturation taking place; and the alkali always prevails. 2. The solution being set in a sand-bath, produced needle-like crystals, which had a sharp bitter taste, exciting a disagreeable sensation in the throat. Their solution turned the tincture of turnsole red, and the liquor from which they were crystallized had the same properties. 3. Having repeated this operation with different quantities of the same crystals, leaving some longer on the fire than others, solutions were obtained, whose acidity was in proportion to the time they had remained on the fire; but during the operation they all emitted the smell of volatile alkali. By calcination this alkali was entirely dissipated, and the residuum was a yellow powder, perfectly similar to that with which the operation was begun. On making use of a retort for the operation, the remaining powder was blue. 4. This salt precipitates the vitriolic salts of iron, copper, zinc, and alum, calcareous nitre, marine mercurial salt, the acetous salts of lead and copper; and with lime-water regenerates tungsten. The vitriolic acid decomposes it, and forms a blue precipitate; the nitrous and marine acids produce a yellow; but no precipitate is occasioned by the Prussian alkali.

Having poured nitrous acid upon a portion of the solution with excess of alkali, a white powder was precipitated, which, after edulcoration, had a taste at first sweet, but afterwards sharp and bitter, and its solution turned the tincture of turnsole red. This, on examination, appeared to be a triple salt formed of the yellow powder, volatile alkali, and the precipitating acid.

The following experiments realize the conjecture of Bergman, that the acid of tungsten is the basis of a particular semimetal.

1. "Having kept 100 grains of the yellow powder (says M. Luyart) in a Zamora crucible well covered, and set the whole in a strong fire for half an hour, it became a spongy mass of a bluish black colour, the surface of which was crystallized into fine points, like plumose antimony, and the inside compact, and of the same colour. It was too hard to be broken in pieces by the fingers; and, when ground, was reduced to a dark-blue colour.

2. "Having mixed 100 grains of the same powder with 100 of sulphur, and put the mixture in a Zamora crucible on a strong fire for a quarter of an hour, it came out a dark-blue mass, which was easily broke by the

Acid of Tungsten.

1501
A kind of semimetal procurable from tungsten.

Acid of
Tungsten.

the fingers; and the inside presented a crystallization like needles as the last, but transparent, and of the colour of a dark lapis lazuli. This mass weighed 42 grains, and when placed on burning coals yielded no smell of sulphur.

3. "Having put another 100-grains of this powder into a Zamora crucible, provided with charcoal, and well covered, and placed it in a strong fire, where it remained an hour and a half, we found, on breaking the crucible after it was cool (A), a button, which fell to powder between the fingers. Its colour was dark brown; and on examining it with a glass, there was seen a congeries of metallic globules, among which some were the bigness of a pin's head, and when broke had a metallic appearance at the fracture in colour like steel. It weighed 60 grains; of course there was a diminution of 40. Its specific gravity was 17.6. Having calcined part of it, it became yellow, with $\frac{2}{80}$ increase of weight. Having put one portion of this substance powdered, in digestion with the vitriolic acid, and another with the marine acid, neither of them suffered more diminution than $\frac{2}{80}$ of their weight; then decanting the liquor, and examining the powder with a glass, the grains were still perceived of a metallic aspect. Both the acid liquors gave a blue precipitate with the Prussian alkali, which let us know that the small diminution proceeded from a portion of iron which the button had undoubtedly got from the powder of the charcoal in which it had been set. The nitrous acid, and aqua-regia, extracted likewise from two other portions the ferruginous part; but besides, they converted them into yellow powder, perfectly similar to that which we used in this operation.

4. "Having put 100 grains of gold and fifty of the yellow powder in a Zamora crucible furnished with charcoal, and kept it in a strong fire for three quarters of an hour, there came out a yellow button, which crumbled in pieces between the fingers; the inside of which showed grains of gold, separated from others of a dark-brown colour. This demonstrated there had not been a perfect fusion, and likewise that this substance was more refractory with gold, since the heat which it endured was more than sufficient to have melted it. The button weighed 139 grains; of course there was a diminution of 11 grains. Having put this button with lead in the cupelling furnace, the gold remained pure in the cupel; but this operation was attended with considerable difficulty.

5. "Having made a mixture of platina and yellow powder in the preceding proportions, and exposed it to a strong fire, with the same circumstances, for an hour and a quarter, it produced a button which crumbled with ease between the fingers, and in which the grains of platina were observed to be more white than usual, and some of them changed sensibly in their figure. This button weighed 140 grains, and of consequence there had been a loss of 10 grains. When calcined, it took a yellow colour, with very little increase of weight; and after washing it to separate the platina, there remained 118 grains of a black colour.

Having placed this portion again to calcine over a strong fire in a muffle, it suffered no sensible alteration in weight or colour; for it neither grew yellow, nor took the brown colour of the platina, but kept the same blackness as before it was calcined. It must be attended to, that in the washings there was not so much care taken to collect all the platina as to deprive it of the yellow colour, and for this reason the water carried off part of the fine black powder; and consequently the increase which the platina preserved, after being washed and calcined the second time, ought to be computed more than the 18 grains which it showed by its weight.

"Having mixed the yellow powder with other metals in the preceding proportions, and treated them in the same manner, the result was as follows:

6. "With silver it formed a button of a whitish-brown colour, something spongy, which with a few strokes of a hammer extended itself easily, but on continuing them split in pieces. This button weighed 142 grains, and is the most perfect mixture we have obtained, except that with iron.

7. "With copper it gave a button of a copperish red, which approached to a dark brown, was spongy, and pretty ductile, and weighed 133 grains.

8. "With crude or cast-iron, of a white quality, it gives a perfect button, the fracture of which was compact, and of a whitish brown colour: it was hard, harsh, and weighed 137 grains.

9. "With lead it formed a button of a dull dark-brown, with very little lustre; spongy, very ductile, and splitting into leaves when hammered: it weighed 127 grains.

10. "The button formed with tin was of a lighter brown than the last, very spongy, somewhat ductile, and weighed 138 grains.

11. "That with antimony was of a dark-brown colour, shining, something spongy, harsh, and broke in pieces easily: it weighed 108 grains.

12. "That of bismuth presented a fracture, which, when seen in one light, was of a dark-brown colour, with the lustre of a metal; and in another appeared like earth, without any lustre: but in both cases one could distinguish an infinity of little holes over the whole mass. This button was pretty hard, harsh, and weighed 68 grains.

13. "With manganese it gave a button of a dark bluish-brown colour and earthy aspect; and on examining the internal part of it with a lens, it resembled impure drops of iron: it weighed 107 grains."

XI. ACID of ANTS.

ETMULLER is among the first authors who mentions the existence of this acid, and speaks of obtaining it by distillation. Nothing of its properties, however, was known, until Margraaf undertook to examine it; of whose experiments we have an account in the Memoirs of the Berlin Academy for 1749. Since his time a number of chemists have prosecuted the subject to

(A) "The first time we made this experiment, we broke the crucible without letting it cool entirely; and as soon as the matter was in contact with the air, it took fire, and its dark brown colour turned instantly yellow."

Acid of
Tungsten.

Acid of
Ants.

to a considerably greater length; but Mr Keir prefers the researches of Arvidson, Bucholtz, and Hermbstadt, to the rest.

1502
Different
methods of
obtaining
this acid.

The acid in question is a natural juice which the insects discharge when irritated, and which is very pungent to the smell as well as taste. Thus it may instantly be perceived on turning up an ant-hill in spring or summer. The *formica rubra* of Linnæus are those insects which have hitherto supplied this acid. Mr Arvidson advises to collect them in the months of June and July, by laying some smooth sticks upon an ant-hill; which being then disturbed, the ants will run upon the sticks in great numbers, and may then be swept off into a vessel containing water until it be full. Hermbstadt collects them in the same manner, but into a dry bottle, to avoid the evaporation of the superfluous liquid. Bucholtz having moistened the inside of a narrow necked glass bottle with honey and water, sunk it into a disturbed ant-hill until the mouth was level with the ground; on which the insects, allured by the smell of the honey, went into the bottle, and could not get out.

For obtaining the acid, Margraaf employed distillation, with the addition of fresh water. Thus he obtained, from 24 ounces of fresh ants, 11 ounces and two drachms of acid, some volatile alkali, empyreumatic oil, and a residuum containing earth and fixed salt. Arvidson made use of two methods: One consisted in distilling the ants when dry; from a pound of which, in this state, he obtained eight ounces of acid besides the empyreumatic oil. His other method was to inclose, in a piece of linen, the ants previously cleaned by washing in water, then to pour boiling water upon them, and to repeat the operation until it could extract no more acid; which is then obtained by squeezing the linen, mixing all the liquors, and filtering them. Thus from a pound of ants he obtained a quart of acid liquor, which tasted like vinegar, but was specifically heavier. By distillation Hermbstadt obtained from a pound of dry ants ten ounces and a half of yellow empyreumatic liquor, which did not taste more strongly acid than the spirit obtained by distilling wood, on which swam three drachms of a brown fetid oil, in all respects like that of hartshorn. In the retort was left a black residuum weighing one ounce six drachms, which exhibited signs of containing volatile alkali. By distilling a pound of ants with three of water, according to Mr Margraaf's method, he obtained an acid liquor and some oil in the receiver; and from the surface of that which remained undistilled, he collected a drachm and an half of fat oil.

The specific gravity of the acid liquor obtained by Mr Arvidson's maceration was 1.0011; that of the same liquor, when distilled, 1.0075; and of the acid concentrated by freezing, 1.0453. According to Bucholtz, the acid liquor thus obtained by maceration did not grow in the least mouldy in the space of four weeks; during which it was allowed to rest in order to free itself perfectly from the impurities it contained. Mr Hermbstadt, however, prefers Margraaf's method of distillation to that of Arvidson's macerations, not only as being a more perfect analysis, but as less laborious; though he finds fault also with Margraaf's method, as diluting the acid too much, and altering it so that it has not the smell of living ants. He

totally disapproves of the method of distilling dried ants, as the acid is thus in a great measure decomposed, and the remainder united with much oil. To avoid all these inconveniences, he contrived another method, namely, to express the juice of the insects; by which means he obtained at once a concentrated liquor fit for distillation. In this way he obtained from two pounds of dried ants 21 ounces and two drachms of juice, which had a pungent and highly acid smell, resembling the vapours of fluor acid; in taste resembling concentrated vinegar and acid of tartar; to which last it might be compared for strength of acidity. By distilling eight ounces of this expressed liquor, he obtained six ounces and a half of clear acid, equal in strength to a very concentrated vinegar.

The acid, when thus procured in purity, has a pungent, not unpleasant smell, a sharp, caustic taste, and an agreeable acidity. It reddens blue paper, syrup of violets, and litmus; blackens the vitriolic acid, and converts part of it into a sulphureous vapour. It is also decomposed by distillation with nitrous acid. Spirit of salt likewise, when dephlogisticated, decomposes it, but not in its ordinary state. It does not form sulphur by an union with phlogiston, but produces inflammable vapours by dissolving iron or zinc. By the assistance of a gentle heat it dissolves foot, but oils with much more difficulty, and powder of charcoal not at all. It does not unite with vitriolic ether; but in distilling a mixture of this acid with spirit of wine, Mr Arvidson saw some traces of an ether, and M. Bucholtz perfectly succeeded in making an ether by means of it. It unites with fixed alkali, forming, according to M. Margraaf, a neutral salt, consisting of oblong deliquescent crystals, from which very little acid could be procured by distillation *per se*; but on adding concentrated oil of vitriol, a very strong and pure acid was obtained; from a mixture of which with spirit of wine, M. Bucholtz readily obtained a true ether. With mineral alkali it forms deliquescent foliated crystals of a saline bitter taste, and soluble in twice their weight of water. With volatile alkali it forms an ammoniacal liquor; which, according to Arvidson, cannot be brought into a dry state; but Mr Arvidson says he has obtained crystals from it, though very thin and deliquescent. Margraaf obtained dry crystals by uniting this acid with chalk or coral; and Arvidson observes that this salt is transparent, cubical, or rhomboidal, nondeliquescent, soluble in eight parts of water, of a bitter taste, and insoluble in spirit of wine. No acid can be obtained from it by distillation *per se*. From a solution of magnesia in this acid, Mr Arvidson obtained some saline particles by deposition, and afterwards an efflorescence of transparent salt rising round a saline mass. This salt had scarcely any taste, was soluble in 13 parts of water, and insoluble in spirit of wine. With ponderous earth the acid formed a cluster of bitter needle-like crystals, which did not deliquesce, were soluble in four times their quantity of water insoluble in spirit of wine, and when burnt gave out a smell like that of burnt sugar, leaving a coal which effervesced with acid. It unites with difficulty to the earth of alum, and can scarcely be saturated with it. It does not precipitate silver, lead, or mercury, from their solution in nitrous acid; whence it seems to have no affinity to the marine

Acid of
Ants.

1503
Properties
of the pure
acid.

Acid of Apples.

1504.

Has an affinity with the acetous acid.

vine acid: and as it does not precipitate lime from the marine acid, it seems to have as little with the vitriolic. From his experiments, however, Margraaf concluded, that the acid of ants, in many respects, though not in all, has a great affinity with the acetous acid. From this it is distinguished by forming different compounds, and likewise by having different affinities. It dissolves the acetous acid also in all instances, and the arsenical acid from cobalt and nickel. It has a greater attraction for fixed alkalies than for lime.

1505
Its effects on metals.

As a solvent it acts but weakly upon copper; not at all, or very little, on silver, lead, tin, regulus of antimony, or bismuth, but strongly on iron or zinc. It dissolves, however, the calces of copper, silver, zinc, and lead, without affecting those of tin, regulus of antimony, or bismuth. The calx of quicksilver, according to Margraaf, is revived by it. According to Arvidson, it crystallizes with iron, zinc, or lead; does not act upon the regulus of antimony, of arsenic, cobalt, or nickel; though it dissolves, their calces as well as the precipitate of manganese. Gold, mercury, and the calx of platina, are not affected by it; but it crystallizes with those of copper, silver, lead, bismuth, and mercury.

1506
Acid procured from various insects.

In its strength of attraction, the acid of ants exceeds those of vinegar, borax, and the volatile sulphureous and nitrous acids. Insects armed with stings, as bees, wasps, and hornets, are likewise said to discharge a very acid juice when irritated; and Mr Bonnet has observed a very strong acid ejected by a caterpillar which he distinguishes by the name of *grande chenille du saule a queue fourchue*. None of these, however, have been as yet particularly examined.

XII. ACID OF APPLES.

1507
Acid of citrons how procured.

THAT the juices of unripe fruits contain some kind of acid has been universally known, and attempts to investigate the nature of it have been made some time ago: but it is to Mr Scheele that we owe the discovery of the particular acid now treated of. He had observed that the juice of citrons contained a particular acid; which, by being united with lime, formed a salt very insoluble in water; and which therefore by means of lime could be readily separated from the mucilaginous part of the juice. By adding vitriolic acid to this compound of lime with the acid juice, almost in the same manner in which he used to procure the acid of tartar, the lime was again separated, and the pure acid of citrons obtained. Proceeding in the same manner with other fruit, he found that an acid, agreeing in every respect with that of citrons, could be procured from the juice of the *ribes grossularia*. Examining the juice which remained after the separation of the former acid from the citrons, he found that it still contained another acid; which being saturated with more calcareous earth, formed a salt easily soluble in water, and therefore remained suspended in the juice. To separate this new salt, he added some spirit of wine, by which the salt was precipitated; but finding that it still contained much gummy matter, he judged that it would be proper to attempt a separation of this gum before he precipitated the salt. For this purpose he evaporated some of the juice of the *ribes grossularia* to the consistence of honey, dissolving

1508
Another acid procured from the juice of fruits.

the mass afterwards in spirit of wine. Thus the acids, which are soluble in the spirit, were easily separated by filtration from the insoluble gum. He then evaporated the spirit, adding to the remainder twice its quantity of water, with as much chalk as was necessary for the saturation. The liquor was next boiled for two minutes; during which the insoluble salt was precipitated, and the liquor separated from it by filtration contained the solution of chalk in the new acid. To this solution he added spirit of wine, which again precipitated the salt, while some saccharine and saccharine matters remained dissolved in the spirit.

Having thus at last obtained the salt in a state of purity, he proceeded to examine its nature; and found, 1. That some of it, spread on his nail, soon dried, and assumed the appearance of varnish. 2. It was very soluble in water, and turned litmus red. 3. When the solution had stood some days exposed to air, it was found to have deposited a number of small crystals, which could only be dissolved by a quantity of boiling water; and this salt was also found to be completely neutralized, so that it yielded its calcareous earth to a fixed alkali. 4. The salt was decomposed by heating *per se* in a crucible, and left a mild calcareous earth. 5. The acid was separated from the earth by adding oil of vitriol diluted with water until gypsum was no longer precipitated, and the new acid was left disengaged, so that it could be separated by filtration. 6. By this operation, however, all the lime was not precipitated, so that the separation of the acid was not complete. 7. He observed that the acid had a greater attraction for lead than for lime; and therefore made use of the method he had formerly discovered for separating the acid of sorrel. To the acid he added a solution of sugar of lead; by which the acid was precipitated along with the lead, and the vinegar was left in the liquor. To this precipitate, cleaned from the acetous acid by filtration, he added vitriolic acid, which expelled the weaker vegetable one, and thus left it quite pure and free from any heterogeneous mixture.

1510
How procured in perfect purity.

The juice of apples, either ripe or unripe, was found to contain no acid of citrons, but a large quantity of the new acid; which, being thus alone, he could more easily procure by a single operation. The best method of procuring this he found to be by saturating the juice of the apples with a solution of fixed vegetable alkali, and pouring a solution of sugar of lead to that of the salt just mentioned. The effect of this was a double decomposition, and a precipitate of lead combined with the new acid. To the edulcorated precipitate he then added a dilute vitriolic acid till he could no longer perceive any sweet taste in the liquor; for the first portions of the vitriolic acid dissolve a part of the calx of lead, and impart a sweetish taste to the liquor, which is sensible, notwithstanding its acidity; but when the quantity of vitriolic acid is sufficient to saturate the whole of the calx, all the metal falls to the bottom, and the sweetness ceases; so that the acid is at once obtained pure.

The acid of apples is possessed of the following properties. 1. It cannot be crystallized, but always remains in a liquid state; or, if much evaporated, attracts the moisture of the air. 2. With fixed alkalies

1511
Properties of it when obtained from the juice of apples.

Acid of
Apples.

of all kinds it forms deliquescent salts. 3. With calcareous earth it forms small irregularly shaped crystals, which cannot be dissolved but in a large quantity of boiling water; but if the acid is superabundant, the salt readily dissolves in lime-water. 4. It is affected by ponderous earth in the same manner as by lime. 5. Earth of alum forms, with the acid of apples, a salt not very soluble in water. 6. With magnesia the acid forms a deliquescent salt. 7. Iron is dissolved into a brown liquor, which does not crystallize. 8. The solution of zinc affords fine crystals. 9. On other metals it has no remarkable effects. From the acid of citrons it differs. 1. The acid of citrons shoots into fine crystals. 2. The acid of apples can be easily converted into that of sugar, which Mr Scheele could not accomplish with that of citrons; though Mr Westrumb has since done it. 3. The salt formed with the citron acid and lime is almost insoluble in water; but that with acid of apples and lime is easily soluble. 4. Acid of apples precipitates mercury, lead, and silver, from their solution in nitrous acid, and likewise the solution of gold, when diluted with water; but the acid of citrons does not alter any of these solutions. 5. The acid of citrons seems to have a greater attraction for lime than that of apples.

1512
Produced
from sugar
by means of
nitrous acid.

It is remarkable that this acid is the first produced in the process for making sugar. If a diluted acid of nitre be drawn off from a quantity of sugar until the mixture becomes a little brown, which is a sign that all the nitrous acid is evaporated, the syrup will be found to have acquired a sourish taste; and if, by means of lime, we next separate all the acid of sugar, another will still remain, which dissolves the calcareous earth. When this acid is saturated with chalk, and the solution filtered and mixed with spirit of wine, a coagulation takes place. On separating the curdled part by means of a sieve, dissolving it in water, and then adding some vinegar of lead, the calx of lead will be precipitated; and if the new acid is then separated from the metal by means of diluted oil of vitriol, it will be found to possess all the properties of the acid of apples, and is indeed the same. The spirit of wine, which has been employed to precipitate the calcareous salt, leaves on evaporation a residuum of a bitter taste, very deliquescent, and similar to the saponaceous extract of the citron.

1513
Experiments with
nitrous acid
on various
substances.

The following are the results of Mr Scheele's experiments with the nitrous acid upon different substances. 1. From gum Arabic he obtained both the acid of apples and of sugar. 2. The same products were obtained from manna. 3. From sugar of milk he obtained not only its own peculiar acid, but those of apples and sugar. 4. Gum tragacanth, during its solution in nitrous acids, lets fall a white powder, which was found to be the acid of the sugar of milk. This gum contained also the acid of apples and of sugar, and a salt formed from lime and the acid of apples. 5. Starch left an undissolved matter; which being separated by filtration, and washed, resembled a thick oil like tallow, which, however, was found to be very soluble in spirit of wine. By distillation he obtained from this oily matter an acid similar to that of vinegar, and an oil which has the smell of tallow, and congeals by cold; and, besides these substances, he found

that starch yielded the acids of apples and sugar. 6. From the root of salep he obtained the acid of apples, with a large quantity of calcareous saccharine salt. 7. Extract of aloes indicated the existence of the acids of sugar and apples, and lost the greatest part of its bitter taste. During the digestion a resinous matter was separated, which smelled like flowers of benzoin, and took fire on being heated in a retort. 8. Extract of colocynth was converted by nitrous acid into a resinous substance, and showed some signs of containing acid of sugar. 9. The extracts of Peruvian bark and of the other plants examined by Mr Scheele, gave both the acids of apples and sugar. 10. These two acids were likewise obtained from an infusion of roasted coffee, evaporated to the consistence of a syrup. 11. The same products were obtained from an extract of rhubarb, which yielded also a resinous matter. 12. Juice of poppies afforded the same results. 13. Extract of galls did the same. 14. The essential oils afforded little or none of the acids; but the oil of parsley seeds seemed to be entirely convertible into them. 15. With a very concentrated acid he was able also to decompose animal substances. From glue he thus obtained fine crystals of acid of sugar, and afterwards acid of apples. Icinglass, whites and yolks of eggs, afforded the same products. From all these substances, especially the last, a fat matter was separated: but it was remarkable that the gas, expelled during the process, was composed of a little fixed air, a great quantity of phlogisticated air, and very little nitrous air; whereas no phlogisticated air is obtained in the usual process for preparing acid of sugar. He observed also, that in the process for this acid, a small quantity of vinegar is found in the receiver. He could not obtain the acid of sugar from the saponaceous extract of urine; but got instead of it a salt, which, when completely purified, resembled exactly the flowers of benzoin. The same salt is precipitated in abundance by adding to the extract of urine a little vitriolic or marine acid; and Mr Scheele had already remarked that the same salt is obtained in the distillation of sugar of milk.

From the various experiments which have been made on this acid, it seems, according to Mr Keir, to be of an intermediate state betwixt acid of tartar and acid of sugar. This, however, ought not to prevent it from being accounted a separate and distinct acid, otherwise we might confound all the vegetable acids with one another. It approaches more nearly to the nature of acid of milk than of any other. From this also, however, it is distinguished, because the salt formed by the union of acid of milk with lime is soluble in spirit of wine, but not that from lime and the acid of apples. According to Mr Hermbstadt, if three parts of smoking nitrous acid be abstracted from one part of sugar, and if the brown acid mass which remains in the retort be diluted with six times its weight of distilled water, and saturated with chalk, two compounds will be formed; one consisting of the acids of tartar and lime, which will precipitate; and the other of lime and the acid of apples, which will remain suspended. If the calcareous earth be precipitated from this latter solution by adding acid of sugar, a pure acid of apples will be left in the liquor.

Acid of
Apples.

1514
Of the nature
of this acid.

and

Acetous Acid. and he further informs us, that this acid of apples may be changed entirely into those of sugar and vinegar, by means of strong nitrous acid.

XIII. ACETOUS ACID.

1515
How to
crystallize
spiritus
Mindereri.

It is generally believed, that the combination of this acid with volatile alkali is altogether incapable of crystallization; but Scheffer and Morveau informs us, that it may be reduced into small needle-shaped crystals, when the spiritus Mindereri is evaporated to the consistence of a syrup, and left exposed to the cold. The salt has a very sharp and burning taste, but a considerable quantity is lost during the evaporation. Westendorf, by adding his concentrated vinegar to volatile alkali, obtained a transparent liquor which did not crystallize. By distillation it went over entirely into the receiver, leaving a white spot on the retort. A saline transparent mass, however, appeared in the receiver under the clear fluid. On separating it from the liquid, and exposing it to a gentle heat, it melted, threw out white vapours, and in a few minutes shot into sharp crystals resembling nitre. These remained unchanged in the cold; but when melted with a gentle warmth, smoked and evaporated. Their taste was first sharp and then sweet.

1516
Salt from
the acetous
acid com-
bined with
calcareous
earth.

The salt formed by uniting acetous acid with calcareous earth has a sharp bitter taste, and shoots into crystals somewhat resembling ears of corn. These do not deliquesce in the air, unless the acid has been superabundant. They are decomposed by distillation *per se*, the acid coming over in white inflammable vapours smelling like acetous ether, somewhat empyreumatic, and condensing into a reddish brown liquor. By rectification this liquor becomes very volatile and inflammable; on adding water, it acquires a milky appearance, and drops of oil seem to swim upon the surface; a reddish brown liquor, with a thick black oil, remain after rectification in the retort. On mixing this calcareous salt with that of Glauber, a double decomposition takes place; we have a gypsum and the mineral alkali combined with acetous acid. By calcination, the mineral alkali may be obtained from this salt in a state of purity. This acetous calcareous salt is not soluble in spirit of wine.

1517
With mag-
nesia.

On saturating this acid with magnesia, and evaporating the liquor, we obtain a viscid saline mass like mucilage of gum arabic, which does not shoot into crystals, but deliquesces in the air. It has a sweetish taste at first, but is afterwards bitter. It is soluble in spirit of wine, and parts with its acid by distillation without addition.

1518
With zinc.

Acetous acid dissolves zinc both in its metallic and calciform state, and even when mixed with other metals. By concentrated vinegar the zinc is dissolved with great heat, sulphureous smell, and exhalation of inflammable matter. By this union we obtain a congealed mass, which on dilution with water shoots into oblong sharp crystals at the first crystallization, and afterwards into crystals of a stellated form. From this liquor indeed crystals of various forms have been obtained by different chemists. Monnet obtained from it a pearl-coloured salt in friable talky crystals; which when thrown on the coals, fulminated a little at first,

and gave a bluish flame, and then melted, letting its acid escape, while a yellow calx remained. Hellot informs us, that this salt by distillation *per se* into water, affords an inflammable liquor, and an oil at first yellow and then green, with white flowers burning with a blue flame. Westendorf obtained no oil in this distillation, but some acetous acid; a sweet-tasted empyreumatic liquor impregnated with zinc; sweet flowers, or sublimate, soluble in water, and burning with a green flame. On applying a stronger heat, the zinc was sublimed in its metallic form, leaving a spongy coal at the bottom of the retort. The solution gives a green colour to syrup of violets, lets fall a white precipitate on the addition of alkalies or an infusion of galls. It is not precipitated by common salt, vitriolated tartar, vitriolic or marine acids, blue vitriol, or corrosive sublimate; but forms a red precipitate when added to solution of gold; a white precipitate with solution of silver; a crystalline pearly precipitate with solution of mercury; and crystalline precipitates with solutions of bismuth and tin. According to Bergman, it is decomposed by acid of arsenic.

Though regulus of arsenic is not soluble in this acid, its calx may be dissolved either in common or distilled vinegar. M. Cadet obtained a smoking liquor by distillation from a mixture of white arsenic and terra foliata tartari. This experiment has been repeated by the chemists of Dijon, and attended with the following curious circumstances. "We digested (say they), in a sand-bath, five ounces of distilled vinegar on white pulverized arsenic; the filtrated liquor was covered, during evaporation, with a white saline crust. Of this substance were formed 150 grains; on which fixed alkali appeared to have no effect, and which was at first considered as pure arsenic. However, a cat, which had swallowed 72 grains of it, was only affected with vomitings that day and the next, and afterwards perfectly recovered. A similar dose was given to a little dog; but as he ran away, the effect it had upon him could not be discovered; but he returned afterwards in good health, and never showed any uneasiness: whence it may be concluded, that vinegar is in some measure an antidote against the pernicious qualities of arsenic.

"On redissolving this saline crust in pure water, filtering and mixing it with liquid alkali, an irregularly crystallized salt was formed in it after a few days standing. By this salt a yellow precipitate was thrown down from the nitrous solution of silver; whereas the solution of arsenic and terra foliata tartari threw down a white one.

"Equal parts of terra foliata tartari and arsenic, distilled in a retort, gave first a small quantity of limpid liquor with a penetrating smell of garlic, and which had the property of reddening syrup of violets; while solution of arsenic in water turns that syrup green. The vinegar which now arose was not saturated with arsenic, but effervesced strongly with fixed alkali, with which it became turbid, but did not let fall any precipitate. On changing the receiver, there came over a reddish brown liquor, accompanied with thick vapours, diffusing an intolerable smell, in which that of arsenic could scarcely be distinguished. On continuing the operation, a black powder sublimed into the neck of the

1519
Its pheno-
mena with
arsenic.

1520
Vinegar
supposed to
be an anti-
dote against
arsenic.

Acetous A- the retort, together with a little arsenic in its metal-
cid. lic form, and a matter which took fire by a lighted
candle like sulphur.

"The red liquor still preserved its property of smoking though cold; diffusing at the same time its peculiar and abominable fœtor, from which the apartment could scarcely be freed in several days. This liquor does not alter the colour of syrup of violets, but effervesces slightly with fixed alkali, letting fall at the same time a yellow precipitate, which, however, disappeared on an attempt to separate it by filtration.

1521
Curious
phosphoric
liquor.

"M. Cadet had observed, that the smoking liquor of arsenic did not kindle at the approach of a lighted candle; but that, on pouring it from the receiver into another vessel, it had kindled the fat lute with which the junctures had been closed, and which had been dried during the operation: but we, being desirous of examining more fully the nature of the red liquor which collects at the bottom, and has the appearance of oil, having decanted that which swims on the top, and poured the remainder on a filter of paper, before many drops had passed, there arose a thick smoke forming a column from the vessel to the ceiling; a slight ebullition was perceived at the sides of the vessel, and a beautiful rose-coloured flame appeared for a few moments. The paper filter was burnt at one side, but most of it was only blackened. After the flame was extinguished, a fat reddish matter remained; which, being melted on burning coals, swelled considerably, emitting a white flame. It then sunk, and left on the coal a black spot, which could not be effaced but by the most vehement fire.

"At the time these observations were made, the liquor had been distilled for three weeks, and the bottle frequently opened. The inflammability could not proceed from the concentration of the vinegar: for the rose-colour of the flame, the precipitation of the sublimate, and the fixity of the spot remaining on the coal, evidently showed that the two substances were in a state of combination; which is also further evinced by the loss of the inflammable property when the liquor was decomposed by fixed alkali.—The smell of the liquor, however, though so intolerably fetid, was attended with no other inconvenience than a disagreeable sensation in the throat, which further strengthens the suspicion that vinegar is an antidote against arsenic.

"The saline brown mass remaining in the retort was partly dissolved by hot water; and the filtrated lixivium was very limpid, but emitted the peculiar smell of the phosphoric liquor. By evaporation it yielded a salt which did not deliquesce in the air, of an irregular shape; and which being put on burning coals, did not smell sensibly of arsenic; lost its water of crystallization; and became mealy and white without being dissipated by heat. On exposing the residuum to the air, it was found next day resolved into a liquor; whence it is probable that most of it was composed of crystallized alkali, having received from the decomposition of the vinegar as much fixed air as was necessary for its crystallization."

1522
Effect of
the acetous
acid on
mercury.

This acid does not act upon mercury in its metallic state, but dissolves the mercurial calces, as red precipitate, turbith mineral, and the precipitate formed

by adding fixed alkali to a solution of mercury in nitrous acid; with all which it forms white, shining, scaly crystals, like those of sedative salt.

Vinegar does not act upon silver in its metallic state, but readily dissolves the yellow calces precipitated from its solution in nitrous acid by microcosmic salt and volatile alkali. By the help of a boiling heat also it very copiously dissolves the precipitate obtained by means of a fixed alkali. The last mentioned solution yields shining, oblong, needle-shaped crystals, which are changed to a calx by means of several acids, especially the muriatic. The silver is thrown down in its metallic form by zinc, iron, tin, copper, and quicksilver.

Though the acetous acid has no effect upon gold in its metallic state, yet a solution of this metal is decomposed by crude vinegar, which produces both a metallic precipitate and dark violet-coloured powder. Distilled vinegar throws down the gold in its metallic form. The precipitate by fixed alkali digested with acetous acid is of a purple colour. This, as well as fulminating gold, is dissolved by Westendorff's concentrated vinegar; the fulminating gold very easily. The solution is of a yellow colour; and with volatile alkali affords a yellow precipitate; with lixivium sanguinis, a blue one; both of which fulminate. The dry salt of gold dissolves in the acetous acid, and produces oblong yellow crystals.

This acid has no effect on fat oils, farther than that, when distilled together, some mixture takes place, as the Abbé Rozier has observed. Neither does distilled vinegar act upon essential oils, though M. Westendorff's distilled vinegar dissolved about a sixth part of oil of rosemary, and about half its weight of camphor. The latter solution was inflammable, and let fall the camphor on the addition of water. The acid dissolves all the true gums, and some of those called gum-resins, after being long digested with them. By long boiling, Boerhaave observes, that it dissolves the bones, cartilages, flesh, and ligaments of animals.

The concentration of this acid may be effected by combining it with alkalies, earths, and metals. By combining it with copper, and then crystallizing and distilling the compound, we obtain the acid in the highest state of concentration in which it is usually met with. To produce this strong acid, we have only to distill verdegris, or rather its crystals in a retort. The operation must be begun by a very gentle fire, which brings over an aqueous liquor. This is to be set aside, in order to procure the more concentrated acid, which comes over with a stronger fire. On changing the receiver, and augmenting the heat, we obtain a very strong acid, which comes over partly in drops, and partly in white vapours. It is called radical vinegar, or sometimes spirit of Venus, and has a very pungent smell, almost as suffocating as that of volatile sulphureous acid. As the last portions of it adhere pretty strongly to the metal, we are obliged to raise the heat to such a degree as to make the retort quite red, in order perfectly to separate them. Hence some part of the metal is raised along with the acid, which, dissolving in the receiver, gives the liquor a greenish colour; but from this it may be easily freed by a second distillation, when it rises with a very gentle heat,

Acetous Acid. and becomes extremely white. Crystals of verdegris afford about one half their weight of radical vinegar; but verdegris itself much less, and of a more oily quality.

1527 If this acid be heated in a wide-mouthed pan, and fire applied to it, it will burn entirely away like spirit of wine. This observation we owe to the count de Lauragais, who has likewise observed, that it is capable of crystallization. This, however, takes place only with the last portions which come over, and the crystals appear in the form of plates or needles. The marquis de Courtrivon, who has repeated and confirmed the experiment of the count de Lauragais, supposes this phenomenon to be owing to a sulphur-like mixture of acetous acid and phlogiston. Leonhardi supposes an analogy between these crystals and the white salt of copper expelled at the end of the operation by the count de Laffone. This salt was at first very white, and fixed on the neck of the retort pretty thick; but unless quickly collected, was soon destroyed by the succeeding vapours. When exposed to the air, it attracts moisture, and runs into a greenish liquid. It is uncommonly light, and in such small quantity, that scarce five or six grains can be collected from a pound of verdegris. Its taste is acid, austere, very unpleasant, and permanent. It readily and totally dissolves in water, and partially in spirit of wine, leaving a yellow powder totally soluble in volatile alkali, and which burns with a green flame. From this salt, volatile alkali acquires a blue colour, and litmus a red one; and thus it discovers itself to be composed of acetous acid and copper.

1528 Difference between radical vinegar and common acetous acid. Experience has shown that radical vinegar differs considerably in its properties from the common acid. It has a greater attraction for alkalies, forms with them more perfect combinations, and is less volatile. M. Berthollet observes, that when vinegar concentrated by frost and radical vinegar, are reduced to equal densities, by adding water to the heavier of the two, they differ very much both in smell and taste. Laffone found, that radical vinegar formed a crystallizable compound with volatile alkali; and Berthollet has observed the same with regard to fixed vegetable alkali. The crystals of the latter with radical vinegar were flat, transparent, and flexible, slowly deliquescent in the air. On comparing the salts formed by the two acids, he found, that the acetous salt rendered the syrup of violets green; but its colour remained unaltered with that made with radical vinegar. The latter also required a stronger fire to expel part of its acid; it was also whiter, and had a less acid taste. On pouring radical vinegar on the acetous salt, the solution afforded, by evaporation and crystallization, a salt perfectly similar to that procured directly from radical vinegar and fixed alkali. On distilling the mixture, the radical vinegar appeared to have expelled the common acetous acid, as the liquor which came over effervesced with vegetable alkali, and formed with it a terra foliata tartari.

“It seems probable (says Mr Keir), that the radical vinegar contains a larger portion of the aerial principle than the common acetous acid; by which it undergoes a change similar to that of marine acid, when brought into that state in which it is said to be de-

N^o 75.

4

phlogisticated. This air it may acquire from the metallic calx, which being deprived of its air is reduced to its metallic state. Those who believe in the phlogiston of metals, may say that the acid is dephlogisticated by imparting its phlogiston to the metal, which is thereby metallized. It appears, however, to be very distinct from common acetous acid, and deserves to have its properties and compounds farther investigated.”

1529 How to obtain it pure from terra foliata tartari. Concentrated acetous acid, of a great degree of strength, may also be obtained by distilling terra foliata tartari with vitriolic acid; but Leonhardi observes, that the acid thus obtained is always more or less contaminated with the volatile acid of sulphur. He observes also, that the method proposed of separating the sulphureous acid by a second distillation from salt of tartar is not effectual, because the sulphureous acid has less attraction for alkalies than the acetous. Wextendorff recommends the neutral salt formed by acetous acid and mineral alkali, instead of the terra foliata tartari. Thus, in the first place, we readily obtain crystals free from the inflammable matter of the vinegar; and, in consequence of this, though we distil it afterwards with concentrated oil of vitriol, no sulphureous taint can be produced. Even supposing this to be the case (he says), it may be removed by a second distillation from some mineral alkali. Mr Keir, however, observes, that “probably all the acids distilled from acetous salts by means of the vitriolic, partake of the property of that procured by distilling crystals of verdegris; and none of them can compare with that from which Mr Loutz obtained acetous ether without addition, as a pure concentrated and unaltered vinegar.”

XIV. ACID of BENZOIN.

1530 M. Lichtenstein's account of its properties. THE properties of this acid have been investigated by M. Lichtenstein, and are as follow. 1. Exposed to the heat of a candle in a silver spoon, it melts as clear as water, without burning, though it is destroyed by contact of flame. 2. When thrown upon coals, it evaporates, without residuum, in a thick white smoke. 3. It is not volatile without a considerable degree of heat. 4. By very slow cooling its aqueous solution yields large crystals, long, thin, and of a feathery shape. 5. It is soluble in the concentrated acids of nitre and vitriol, but separates from them, without decomposition, on the addition of water. 6. By the other acids it cannot be dissolved without heat, and separates from them also without any change, merely by cooling. 7. It is copiously dissolved by spirit of wine, and precipitated from it on the addition of water. 8. With alkalies it forms neutral salts, very soluble in water, and of a sharp saline taste. With vegetable alkali it forms crystals of a pointed feathery form; with mineral alkali it yields larger crystals, which fall into powder on being exposed to the air; and with volatile alkali it is difficultly crystallizable into small, feathery, and deliquescent crystals. It is separable from alkalies by the mineral acids. 9. With calcareous earth it forms white, shining, and pointed crystals, not easily soluble, and which have a sweetish taste without any pungency. 10. With magnesia it

¹⁵³² *Acetous Acid.* small feathery crystals are formed, of a sharp saline taste, and easily soluble in water. 11. An astringent salt is formed with earth of alum.

All these earthy salts are easily decomposed by the mineral acids as well as by alkalies. The acid of benzoin itself reddens litmus, but has little effect upon syrup of violets.

¹⁵³³ Effects of nitrous acid upon it.

Messrs. Hermbstadt and Lichtenstein have both tried the effects of nitrous acid upon that of benzoin. In this operation, however, a great obstacle arose from the volatility of the acid of benzoin, which prevented it from bearing any considerable heat without passing over into the receiver. By repeated distillations, however, the acid of benzoin, diminished in its volatility, assumed a darker colour, and acquired a bitterish taste. A coal was also left at the bottom; and, at the end of the third operation, when the nitrous acid had been all drawn off, M. Hermbstadt observed, that some brown drops came over which had the appearance of a dark-coloured transparent oil, soluble in distilled water, emitting acrid fumes, and having a very caustic taste. On distilling this acid liquor a second time, a yellow saline mass was obtained, which, when dissolved in distilled water, formed a fluid acid, which precipitated a solution of sugar of lead and lime-water. On examining the charred residuum left in the retort, he observed, that, after calcination, some of the earth had been vitrified, while another was of a soft consistence, and had acquired a caustic taste. From a mixture of the above-mentioned dark-brown acid and spirit of wine, he obtained an ether, which differed from the nitrous in being much less volatile, and smelling like bitter almonds.

From this residuum Mr Lichtenstein obtained a resinous substance, to which he ascribes the volatility of the acid of benzoin, as well as the smell of bitter almonds already mentioned.

¹⁵³² Acid of benzoin procurable from Peruvian balsam and urine.

Scheele failed in his attempt to obtain ether from flowers of benzoin and spirit of wine; but, by adding a little spirit of salt, he obtained a kind of ether which fell to the bottom. On dissolving this in alkalized spirit of wine, and drawing off the latter by distillation, he obtained from it a quantity of flowers of benzoin. From Peruvian balsam also Lehman obtained a quantity of the acid of benzoin. It may also be procured from urine, either by precipitation, from the saponaceous extract (A), or by repeatedly distilling from it spirit of nitre, as in the preparation of acid of sugar. In the urine it is found combined with volatile alkali, by which it becomes soluble in spirit of wine.

XV. SEBACEOUS ACID.

THIS is said to have been first discovered by Mr Gruitzmacker, who published an account of it in 1748. It was afterwards more accurately treated of by Mr Rhades in 1753. Its properties were investigated by Messrs Segner and Knappe in 1754; and afterwards more fully by Dr Crell, of whose discoveries an account is given in the Philosophical Trans-

VOL. IV. PART II.

actions for 1780 and 1782. It is found not only in the fat of all animals, but in spermaceti, the butter of cocoa, and probably in other vegetable oils. In several respects it seems analogous to the marine acid; but in others it is remarkably different, particularly in precipitating a solution of corrosive sublimate. It is probable, however, that its principles are the same with those contained in all other vegetable and animal acids; and this opinion is supported by what happens on treating tallow in the usual manner for obtaining acid of sugar; for thus, not the sebaceous, but the saccharine acid is found to be produced. It has a very great strength of attraction, and by means of heat decomposes even the vitriolic salts themselves; but in the moist way is expelled by the three mineral acids, though it expels all the vegetable ones, as well as those of fluor and arsenic. Its most remarkable property is its effect on tin. The filings of this metal, especially with the assistance of heat, are corroded by it into a yellow powder, and at the same time give out a very fetid smell. The solution, though filtered, still continues turbid, and deposits more yellow powder, acquiring at the same time a fine rose-red colour. By adding water to this yellow powder, a white deliquescent salt may be obtained, and a similar one obtained by dissolving a yellow powder precipitated by this acid from solution of tin in aqua regia.

It corrodes lead rather than dissolves it; but dissolves a considerable quantity of minium, and changes the rest to a white powder. This solution is sweetish, and is not precipitated by common salt. The metal is precipitated by sebaceous acid from the nitrous, in white needle-like crystals, easily soluble in water. A like precipitation takes place in solution of sugar of lead; but the precipitate is still soluble in strong vinegar, provided it be not adulterated with oil of vitriol. In its elective attractions it agrees with the acids of apples and of fluor, preferring magnesia to fixed alkali.

XVI. ACID OF GALLS.

THOUGH it has for a long time been known that the infusion of galls has the property of reddening vegetable juices, dissolving iron, and decomposing liver of sulphur, these effects were generally ascribed to its astringency. Of late, however, it has been found, that besides this astringent principle a true acid exists in galls; and to this, rather than to the astringent principle, are we to ascribe the properties of galls in striking a black with solution of vitriol, &c.

To separate the acid from the other matters contained in the galls, we must add fixed alkali to a decoction of them; by which means the astringent matter will be thrown down, and the acid remain in the liquor joined to the alkali. The precipitate, washed with clean water, dried, and redissolved, blackened a solution of vitriol but faintly, and no more than what may be supposed to proceed from some remaining acid, which could not be abstracted. This is proved by di-

tion.

stillling the astringent matter in question, when an acid liquor comes over, which has the property of blackening solution of vitriol. Scheele has observed, that when galls in substance are exposed to distillation, an acid liquor rises of an agreeable smell, without oil, and afterwards a kind of volatile salt, which is the true acid of the galls. Hence he infers, that this salt is contained ready formed in the galls themselves; but so much involved in some gummy or other matter, that it cannot be easily obtained separately.

1539
Properties
of this acid.

The acid of galls is capable of being separated by crystallization. In an infusion made with cold water, Scheele observed a sediment which appeared to have a crystalline form, and which was acid to the taste, and had the property of blackening solution of vitriol. By exposing the infusion for a long time to the air, and removing from time to time the mouldy skin which grew upon it, a large quantity of sediment was formed. On redissolving this in warm water, filtering and evaporating it very slowly, an acid salt was obtained in small crystals like sand, which had the following properties: 1. It tasted acid, effervesced with chalk, and reddened litmus. 2. Three parts of boiling water dissolved two of the salt; but 24 parts of cold water were required to dissolve one. 3. It is likewise soluble in spirit of wine; four parts of which are required to dissolve one of the salt when cold, but only an equal quantity when assisted by a boiling heat. 4. The salt is destructible by an open fire, melts and burns with a pleasant smell, leaving behind a hard insoluble coal, which does not easily burn to ashes. 5. By distillation an acid water is first obtained without any oil; then a sublimate, which remains fluid while the neck of the retort is hot, and then crystallizes. This sublimate has the taste and smell of flowers of benzoin; is soluble in water and in spirit of wine; reddens litmus; and precipitates metallic solutions of the following colours, viz. gold of a dark brown; silver of a grey colour; copper of a brown; iron of a black; lead of a white colour; mercury of an orange; bismuth, lemon-coloured. The acid of molybdæna became yellow coloured, but no precipitate ensued. Solutions of various kinds of earths were not altered; but lime water afforded a copious grey-coloured precipitate. 6. By treating this acid with that of nitre, in the manner directed for producing acid of sugar, it was changed into the latter.

XVII. IDENTITY of the VEGETABLE ACIDS.

1540
Mr Keir's
objections
to the opi-
nions on
this subject.

ON the proofs of the identity of the vegetable acids with one another, Mr Keir makes the following remarks: "The experiments and observations which have been made, prove evidently a strong analogy between the acetous acid, spirit of wine, tartar, and acid of sugar; and they seem to show the existence of a common principle or basis in all of them, modified either by the addition of another principle not common to all of them, or by different proportions of the same principle. None of the opinions on this subject, however, are quite satisfactory. The production of the acetous acid by treating spirit of wine with other acids, does not prove that the acetous acid was contained in the spirit of wine, but only in concurrence with them, that they contain some common prin-

ciple. There is no fact adduced to support Morveau's opinion, that fixed air is absorbed during the acetous fermentation; or that the presence of this fixed air is necessary. The decomposition of all vegetable acids by heat, and the production therefrom of fixed and inflammable gases, show that these acids contain some of the same principles as these elastic fluids, but do not prove that the gases existed in the fluids. We have good reason to believe that acetous acid does not contain any fixed air ready formed; for it yields none when vitriolic acid is added to it, or to foliated earth; nevertheless, my opinion that vegetable and animal acids are, by heat, in a great measure convertible into fixed air, seems to be sufficiently proved by experiments. Thus Hales has shown the great quantities of this gas which tartar yields on distillation. Berthollet has obtained the fixed and inflammable gases from foliated earth; and Dr Higgins has verified this experiment, and deduced the quantities. From 7680 grains of foliated earth, the Doctor obtained

Caustic alkali	-	3862.994 grains.
Fixed air	-	1473.564
Inflammable air	-	1047.6018
Oily matter retained in the residuum	-	78
Oil	-	182
Water condensed	-	340
Deficiency attributed chiefly to water	-	726.9402"

As fixed and inflammable gases may be obtained from every vegetable substance by fire, nothing can be inferred from these experiments to explain particularly the nature of the acetous acid, excepting that it contains some of the inflammable matter common to the vegetable kingdom, and especially of the matter common to vegetable acids; all which also, when analysed, furnish large quantities of these two gases.

"Although we are far (adds our author) from the knowledge requisite to give a complete theory of the acetous fermentation, yet it may be useful to explain the ideas that appear most probable. In all the instances that we know of the formation of acids, whether effected by combustion, as the acids of sulphur and phosphorus, or by repeated abstractions of nitrous acid, as in the process for making acid of sugar, a very sensible quantity of pure air is absorbed. In the case of combustion we know, from the weight acquired, that there is a great absorption of air; and in the latter case, of acids being produced by application of nitrous acid, as this acid consists of nitrous acid and pure air and as in these operations a quantity of the nitrous gas is expelled, there seems little doubt but that there also the pure air of the nitrous acid is united with the substance employed in the formation of the new acid. Hence, from all that we know, the absorption of air takes place in all acidifying processes. But it also actually takes place in the acetous fermentation, as has been observed, particularly by the Abbe Rozier; and it is generally known, that air is necessary to the formation of vinegar. The next question is, What is the basis? And from the experiments already related, of forming the acetous acid by means of spirit of wine, it seems probable, either that this spirit is the basis of the acetous acid, or that it contains this basis: and from the convertibility of the acids of tartar and of sugar

fugar into the acetous acid by the processes above de-
scribed, it seems probable that these also contain the
same common basis; which, being united with a de-
termined quantity of pure air, forms acid of tartar;
with a larger quantity, acid of fugar; and with a still
larger, the acetous acid.

"An inflammable spirit is said to appear at the end
of the distillation of radical vinegar from verdigris.
Now, if the ardent spirit were contained in the verdi-
gris, as it is more volatile than the acid, it ought to
come over first; but as it appears only towards the
end of the distillation, it seems to be formed during
the operation; and I imagine, that the metal, when
almost deprived of its acid, attracts some of the air of
the remaining acid; and the part or basis of the acid
thus deprived of its air becomes then an inflammable
spirit, and in some cases an oil appears. But as the
quantity of acid thus decomposed is very small, and
little air of consequence remains united with the me-
tallic part of the verdigris, the copper appears rather
in a metallic than calciform state after the operation.
But zinc, during its solution in concentrated vinegar,
decomposes the acid as it does the vitriolic and other
strong acids, and accordingly inflammable vapours are
produced; and what is remarkable, these vapours have
a sulphureous smell. Iron always, during its solution
in concentrated vinegar, produces an expulsion of in-
flammable vapours; which, however, do not explode
like inflammable gas.

"We must not imagine that we are yet able to ex-
plain completely what passes in the acetous fermenta-
tion, or that the acetous acid is a compound of mere
spirit and pure air. Besides this combination of spirit
and air, it is observed, that a precipitation always takes
place before the fermentation is completed, of some
mucilaginous matter, which disposes the vinegar to
putrefy, and from which it therefore ought to be care-
fully separated. Stahl affirms, that without a depo-
sition of such sediment, vinegar cannot be made from
fugar, wine, or other juice. Besides the matter that
is deposited, probably as much remains in the liquor
as can be dissolved therein; for, by distillation, much
of a similar extractive matter is left in the retort.
What the nature of this matter is, and how it is form-
ed, has not yet been examined. Though distillation
frees the acid from much of this extractive substance,
yet we have no reason to believe that we have ever ob-
tained it entirely free from inflammable matter; as
it retains it even when combined with alkalies and
with metals. When fugar of lead and other acetous
salts are distilled with a strong heat, the substances re-
maining in the retort have been observed to possess the
properties of a pyrophorus; and this will happen
whatever pains have been taken to purify the vinegar
employed. See the article PYROPHORUS. This fact
shows the existence of an inflammable matter in this
acid; and which may perhaps be essential in its com-
position, and necessary to its properties. Although
fermentation is the usual mode of obtaining acetous
acid, yet it appears from the instances observed by
latter chemists, that it is not essential to its formation,
but that it is also formed in various chemical processes;
and the acids obtained by distillation from woods,
wax, &c. are very analogous to vinegar. It appears
also on treating the acid of fugar with nitrous acid, as has

been observed both by Westrumb and Scheele. The
latter further acquaints us, that he obtained it in ana-
lysing a tallow like oil, which remained undissolved
upon digesting starch in nitrous acid. As acid of fu-
gar also may be obtained from a variety of animal sub-
stances, and as this acid is convertible into the ace-
tous, we have one reason more added to many others,
to prove that the matters of vegetable and animal sub-
stances are not capable of any chemical distinction."

Addition
to Sect. I.
§ 20.

XVIII. ADDITION to Sect. I. § 20. concerning the Volatility of a Mixture of MARINE and NITROUS ACIDS.

THIS is much less sensible when the acids are weak
than when they are concentrated. On mixing the
two when moderately smoking, and which had remain-
ed for a long time separate without occasioning any
disturbance, a vastly smoking aqua-regia has been pro-
duced, which would either drive out the stopple, or
burst the bottle in warm weather. On distilling a
pretty strong nitrous acid from sal ammoniac, M.
Beaumé observed, that the vapours which came over
were so exceedingly elastic, that notwithstanding every
precaution which could be taken in such a case, the
distillation could not be continued. By letting this
escape, however, Mr Cornette observed, that the
distillation of these two substances may be carried on
to the end without any inconvenience, and the aqua-
regia will then be no longer troublesome.

1548
How to de-
rive aqua-
regia of its
volatility.

XIX. TEST for ACIDS and ALKALIES.

THE general method recommended for discovering
a small quantity of acid or alkali in any liquid, is by
trying it with any vegetable blue, such as syrup of
violets; when, if the acid prevails in the liquor, the
syrup will acquire a red colour, more or less deep ac-
cording to the quantity of acid; or if the alkali pre-
vail, it will change the syrup green in like proportion.
Since the late improvements in chemistry, however, the
syrup has been found deficient in accuracy, and the
infusion of turnsole, or of an artificial preparation
called litmus, have been substituted instead of it.
The infusion of litmus is blue, and, like syrup of vio-
lets, becomes red with acids. It is so sensible that it
will discover one grain of oil of vitriol though mixed
with 100,000 of water. Unfortunately, however, this
infusion does not change its colour on mixture with al-
kalies; it is therefore necessary to mix it with just as
much vinegar as will turn the infusion red, which will
then be restored to its blue colour by being mixed with
any alkaline liquor. The blue infusion of litmus is al-
so a test of the presence of fixed air in water, with
which it turns red, as it does with other acids.

1549
Inaccuracy
of the com-
mon tests.

The great sensibility of this test would leave very
little reason to search for any other, were it always an
exact test of the point of saturation of acids and alka-
lies; but, from the following fact, this appears to Mr
Watt to be dubious. A mixture of phlogisticated ni-
trous acid with an alkali will appear to be acid by the
test of litmus, when other tests, such as the infusion of
the petals of the scarlet rose, of the blue iris, of vio-
lets, and of other flowers, will show the same liquor to
be alkaline, by turning green so evidently as to leave
no room to doubt.

When Mr Watt made this discovery, the scarlet ro-
ses,

Test for Acids and Alkalies.

1550
Red cabbage answers the purpose best.

1551
How to prepare it for use.

ses, and several other flowers, whose petals change their colour by acids and alkalies, were in flower. Having stained paper with their juices, he found that it was not affected by the phlogisticated nitrous acid, excepting in so far as it acted the part of a neutralizing acid; but he found also, that paper stained in this manner was much less easily effected than litmus was; and that, in a short time, it lost much of the sensibility which it possessed at first; and having occasion in winter to repeat some experiments in which the phlogisticated nitrous acid was concerned, he found his stained paper almost useless. Searching, therefore, for some other vegetable which might serve for a test at all seasons of the year, he found the red cabbage to answer his purpose better than any other; having both more sensibility with regard to acids than litmus, being naturally blue, and turning green with alkalies, and red with acids; to all which is joined the advantage of its being no farther affected by the phlogisticated acid of nitre than as it acts as a real acid.

To prepare this test, Mr Watt recommends to take the freshest leaves of the cabbage; to cut out the large stems, and mince the thin parts of the leaves very small; then to digest them in water at about the heat of 120 degrees for a few hours, when they will yield a blue liquor; which, if used immediately as a test, will be found to possess great sensibility: but as in this state it is very apt to turn putrid, some of the following methods must be used for preserving it.

1. After having minced the leaves, spread them on paper, and dry them in a gentle heat; when perfectly dry, put them up in glass bottles well corked; and, when you want to use them, acidulate some water with vitriolic acid, and digest or infuse the dry leaves in it, until they give out their colour; then strain the liquor through a cloth, and add to it a quantity of fine whiting or chalk, stirring it frequently, until it becomes of a true blue colour, neither inclining to green nor purple; when you perceive that it has acquired this colour, filter it immediately; otherwise it will become greenish by standing longer on the whiting. This liquor will deposit a small quantity of gypsum, and, by the addition of a little spirit of wine, will keep good for some days; but will then become somewhat putrid and reddish. If too much spirit is added, it destroys the colour. If the liquor is wanted to keep longer, it may be neutralized by a fixed alkali instead of chalk.

2. As thus the liquor cannot be long preserved without requiring to be neutralized afresh just before it is used; and as the putrid fermentation which it undergoes, and perhaps the alkalies or spirit of wine mixed with it, seem to lessen its sensibility; in order to preserve its virtues while kept in a liquid state, some fresh leaves of the cabbage, minced as above directed, may be infused in a mixture of vitriolic acid and water, of about the degree of acidity of vinegar; and it may be neutralized, as it is wanted, either by means of chalk, or of the fixed or volatile alkali. It must be observed, however, that, if the liquor has an excess of alkali, it will soon lose its colour, and become yellow; from which state it cannot be restored; care should therefore be taken to bring it very exactly to a blue, and not to let it verge towards a green.

3. In this manner, Mr Watt prepared a red infusion

of violets; which, on being neutralized, formed a very sensible test, though he did not know how long these properties would be preserved; but he is of opinion that the coloured infusions of other vegetables may be preserved in the same manner by the antiseptic power of the vitriolic acid, in such a manner as to lose little of their original sensibility. Paper fresh stained with these tests, in their neutral state, has sufficient sensibility for many experiments; but the alum and glue which enter into the preparation of writing paper, seem, in some degree, to fix the colour; and paper which is not sized becomes somewhat transparent when wetted; which renders small changes of colour imperceptible. Where accuracy is required, therefore, the test should be used in a liquid state.

4. Our author has found that the infusion of red cabbage, as well as of various flowers in water, acidulated by means of vitriolic acid, are apt to turn mouldy in the summer season, and likewise that the moulding is prevented by an addition of spirit of wine. He has not been able to ascertain the quantity of spirit necessary for this purpose, but adds it by little and little at a time until the process of moulding is stopped.—Very sensible tests are afforded by the petals of the scarlet rose, and of the pink coloured lychnis treated in the above-mentioned manner.

XX. VOLATILE ALKALI.

MR HIGGINS claims the first discovery of the constituent parts of volatile alkali, or at least of an experiment leading to it. "About the latter end of March 1785 (says he), I found that nitrous acid poured on tin filings, and immediately mixed with fixed vegetable alkali, generated volatile alkali in great abundance: so singular a fact did not fail of deeply impressing my mind, though at the time I could not account for it. About a fortnight after, I mentioned the circumstance to Dr Brocklesby. He told me he was going to meet some philosophical gentlemen at Sir Joseph Banks's, and desired I would generate some alkali to exhibit before them: accordingly I did; and had the pleasure of accompanying him thither. The December following I mentioned the fact to Dr Caulet, and likewise the copious generation of volatile alkali from Prussian blue, vegetable alkali, and water; on which we agreed to make a set of experiments upon the subject. At present I shall only give an account of the following, which drew our particular attention. Into a glass cylinder, made for the purpose, we charged three parts of alkaline air, and to this added one part of dephlogisticated air; we passed the electrical spark repeatedly in it, without apparently effecting the smallest change. When it had received about 100 strong shocks, a small quantity of moisture appeared on the sides of the glass, and the brass conductors seemed to be corroded: when we had passed 60 more shocks in it, the quantity of moisture seemed to increase, and acquire a greenish colour, though at this time the column of air suffered no diminution. On examining the air, it burned with a languid greenish flame, from which we inferred that the dephlogisticated air was totally condensed: it still retained an alkaline smell; and the alkaline part was not readily absorbed by water.

True com-
position of
volatile al-
kali.

"From Mr Cavendish's famous discovery of the constituent parts of water we could readily account for the loss of the dephlogisticated air in this experiment; but the quantity of water was more than we could expect from this: therefore water must have been precipitated from the decomposed alkali; for volatile alkali, from its great attraction to water, must keep some in solution, even in its aeriform state. From the above circumstances it might be expected, that a contraction of the column of air should take place; but it must be considered, that the union took place gradually in proportion as the alkali was decomposed; and that, in this case, the expansion must equal the condensation. During the spring of 1786, I had often an opportunity of mentioning different facts to Dr Austin relating to volatile alkali, who at that time was too much engaged to pay attention to the subject. In the end of August 1787, he gave me an account of a set of experiments which he had made, and which actually proved, that volatile alkali consists of light inflammable and phlogisticated airs; not knowing at that time what Messrs Housman and Berthollet had done. Without depreciating the merit of these two gentlemen, Dr Austin has an equal claim to the discovery, laying aside priority; as his experiments are as decisive as theirs. Dr Priestley made the first step towards our knowledge of volatile alkali."

XXI. PRUSSIAN BLUE.

1557
Woulfe's
test for mi-
neral wa-
ters.

1558
Effect of it
on various
metallic so-
lutions.

THE acid of this substance, as far as it contains an acid, is supposed to be that of phosphorus. Mr Woulfe proposed a test of this kind for discovering iron in mineral waters, which, he observed, would not be affected by acids; but the lixivium described by him had the bad property of letting fall the Prussian blue it contains in a few weeks. The precipitate of copper, however, treated again with alkali, retained this property upwards of nine months. The volatile alkali, he observes, is dissolved by the Prussian acid; and the crystals deposited are rendered blue by the colouring matter, though the colour at first is lost by the union of the alkali with the substance already made. The metals were precipitated by this test of the following colours: Gold of a brownish yellow, the precipitate afterwards becoming of a full yellow: platina of a deep blue, but when quite pure, of a yellow colour, turning slightly green. Silver in the nitrous acid was precipitated of a whitish colour; copper from all the different acids was precipitated of a deep brown colour, the liquid remaining greenish; green vitriol let fall a deep blue powder, leaving a colourless lixivium; sugar of lead and muriated tin gave a white powder; nitrated mercury a white or yellowish precipitate; the Illfeld manganese a brownish, but that from Devonshire a blue, which first became ash-coloured and then reddish. Nitrated bismuth afforded a white precipitate, and the lixivium was slightly green: muriated antimony yielded a white precipitate, with a yellowish lixivium: vitriolated zinc a whitish: cobalt in aqua-regia a reddish white powder: the precipitate of arsenic and the different earths was commonly white.

XXIII. NEW CHEMICAL NOMENCLATURES.

1. Of that proposed in 1787 by Messrs Morveau, Berthollet, Fourcroy, and Lavoisier.

New Che-
mical no-
mencla-
tures.

WHEN this nomenclature was first published, M. Lavoisier informs us, that some blame was thrown upon the authors for changing the language, which had received the sanction of their masters, and been adopted by them. In answer to this, however, he urges, that Messrs Bergman and Macquer had expressed a wish for some reformation in the chemical language. Mr Bergman had even written to M. Morveau on the subject in the following terms. "Show no favour to any improper denomination: Those who are already possessed of knowledge, cannot be deprived of it by new terms; those who have their knowledge to acquire, will be enabled by your improvement on the language of the science to acquire it sooner."

1559
Bergman's
letter to
Morveau
on this sub-
ject.

The following is M. Lavoisier's explanation of the principles on which his new language is composed. "Acids consist of two substances, belonging to that order which comprehends such as appear to us to be simple substances. The one of these is the principle of acidity, and common to all acids; from it therefore should the name of the class and genus be borrowed: The other, which is peculiar to each acid, and distinguishes them from one another, should supply the specific name. But in most of the acids, the two constituent principles, the acidifying and the acidified, may exist in different proportion, forming different degrees of equilibrium or saturation; this is observed of the sulphuric and sulphureous acid. These two states of the same acid we have expressed by varying the termination of the specific name.

1560
Lavoisier's
explanation
of the new
nomencla-
ture.

"Metallic substances, after being exposed to the compound action of air and fire, lose their metallic lustre, gain an increase of weight, and assume an earthy appearance. In this state they are, like acids, compound bodies, consisting of one principle common to them all, and another peculiar to each of them. We have therefore in like manner classed them under a generic name, derived from the principle which is common to them all. The name which we have adopted is *Oxide*: The peculiar names of the metals from which they are formed, serve to distinguish these compounds from one another.

"Combustible substances, which, in acids and metallic oxides, exist as specific and peculiar principles, are capable of becoming, in their turn, the common principle of a great number of substances. Combinations of sulphur were long the only compounds of this sort known: but of late the experiments of Messrs Vandermonde, Monge, and Berthollet, have shown that coal combines with iron and perhaps with various other metals; and that the results of its combination with iron are, according to the proportions, steel, plumbago, &c. It is also known from the experiments of M. Pelletier, that phosphorus combines with many metallic substances. We have therefore arranged these different combinations together under generic names, formed from the name of the common substance, with a termination indicating this analogy; and have distinguished them from each other by specific names derived from the names of the peculiar substances.

"It

New Chemical Nomenclatures.

"It was found somewhat more difficult to form a nomenclature for the compounds of those three simple substances; because they are so very numerous, and still more, because it is impossible to express the nature of their constituent principles, without using more compound names. In bodies belonging to this class, such as neutral salts for instance, we had to consider, 1. the acidifying principle common to them all; 2. the acidifiable principle which peculiarizes the acid; 3. the saline, earthy, or metallic base, which determines the particular species of the salt. We have derived the name of each class of salts from that of the acidifiable principle, common to all the individuals of the class; and have then distinguished each species by the name of the *saline, earthy, or metallic* base peculiar to it.

"As salt, consisting of any three principles, may, without losing any of these principles, pass through different states by the variation of their proportions; our nomenclature would have been defective without expressions for these different states. We have expressed them chiefly by a change of termination, making all names of salts in the same state to end with the same termination."

2. Nomenclature by M. Wiegleb.

1562
Mr Wiegleb's nomenclature.

In Wiegleb's General System of Chemistry translated by Hopson, we have another nomenclature formed on different principles. In this he gives to fixed vegetable alkali the name of *Spodium*, from the Greek word σποδον (*asbes*). The mineral alkali he calls *natrum*, the name by which it was anciently distinguished; and the volatile alkali *ammonium*, from sal ammoniac which contains it in great quantity. The compound salts may be distinguished into double, triple, and quadruple; though, in the scheme given in the work, the first division is omitted, as tending only to create confusion. The irregular salts, consisting of those which are triple and quadruple, are admitted. Such as are imperfect by reason of an excess of acid, he says, are best denominated by converting the adjective, expressive of the base, into a participle; a practice which, on many occasions, though countenanced by the authority of a late eminent writer, seems awkward and stiff. The excess of acid is denominated by the word *hyperoxys*, and a defect of it by *hypoxys*. Hence his denominations are formed in the following manner.

Salts with excess of acid. Cream of tartar, or *tartarus spodatus*, or *tartaroxys spodicus*. Acid vitriolated tartar, or *vitriolum spodatum*, *vitrioloxys spodicus*.

The salts which are imperfect from a defect of acid

have their denominations by mentioning the base before the acid, and expressing the former substantively, the latter adjectively. Thus,

Salt of tartar, aerated vegetable alkali, spodium aerocraticum,	{ Oxyspodium, aerocraticum.
Aerated volatile alkali, ammoniacum aerocraticum,	{ Oxyammonium aerocraticum.
Chalk, or calx aerocratica,	{ Oxycalcitis aerocraticus.
Borax, or natrum boracicum,	{ Oxynatrum boracicum.

With respect to other terms, Mr Wiegleb expresses the acid with which any base is combined, by the termination *cratia*, from the Greek κρατος (*robur*), added to it; excepting only those with the nitrous and muriatic acids; and these (for what reason does not appear) he calls *Aponitra* and *Epimuria*. His genera of salts are as follow.

1. Vitriols (*Sulphurocratia*).
2. Nitrates (*Aponitra*).
3. Murias (*Epimuria*).
4. Boraxes.
5. Fluorocrates.
6. Arsenicrates.
7. Barylithicrates, (those with acid of tungsten).
8. Molybdænocrates.
9. Photocrates, (with acid of phosphorus).
10. Electocrates.
11. Oxycrates, (with the acetous acid); or *epoxycrates*, (with the aerated acid).
12. Tartars; or, with the acid changed by fire, *pyro-tartars*.
13. Oxalidicrates.
14. Cecidocrates (with acid of galls).
15. Citriocrates.
16. Melicrates (with the acid of apples).
17. Benzicrates.
18. Xylocrates.
19. Gummicrates.
20. Camphoricrates.
21. Aerocrates.
22. Galacticrates.
23. Gala-melicrates (with acid of sugar of milk).
24. Myrmecicrates.
25. Cyanocrates (with the colouring matter of Prussian blue).
26. Steatocrates.
27. Bombycicrates.
28. Zoolithocrates, (with acid of calculus).

On the subject of nomenclatures it is obvious to remark, that whatever may be the defects of the old one, we are ready to be involved in much greater difficulties by the introduction of a new one. Or supposing a new language to be adopted, where would be the security for its permanence? That which appears most specious at one period, may still be superseded by the refinements of another; and colourable pretensions would never be wanting to successive innovators. Hence a continual fluctuation, and an endless vocabulary. As the nomenclature first above mentioned, however, has attracted no small degree of attention, we shall here subjoin a scheme of it, as well for the satisfaction of our readers in general, as for the gratification of those in particular who may have imbibed the doctrines of its authors.

TABLE, showing the Manner in which Natural Bodies, considered in a Chemical View, may be divided into Classes; with their several Subdivisions; their Properties defined; and the Manner in which they are obtained, pointed out.

NATURAL BODIES, considered as the Objects of Chemistry, may be divided into the following Classes, viz.
1. SALTS. 2. EARTHS. 3. METALS. 4. INFLAMMABLES. 5. WATERS. 6. AIRS.

I. SALTS.

THESE are soluble in water, sapid, and not inflammable. They are either ACIDS or ALKALIES.

- I. *ACIDS* are distinguished by turning syrup of violets red, or forming with alkalies neutral salts; and are supposed to consist of dephlogisticated air condensed, as their acidifying principle. The different acids yet known are,
 1. *Vitriolic, fixed.* The most ponderous of all fluids next to mercury, the most fixed in the fire, and the most powerful as a solvent of all the acids. Obtained chiefly from sulphur by inflammation.
 2. *Vitriolic, volatile.* Obtained also from sulphur by inflammation; air being admitted during the process. It acts less powerfully as a solvent than when in its fixed state.
 3. *Nitrous, or Aquafortis:* a volatile fluid, generally met with of a reddish colour, and emitting noxious fumes, when in its concentrated state; though this is found not to be essential to it, but owing to a mixture of phlogiston. In its pure state it is almost as colourless as water, and smokes very little. It is next in strength to the vitriolic acid, and obtained chiefly from nitre. It consists of dephlogisticated and phlogisticated air condensed, and may be obtained by taking the electric spark for a long time in a mixture of these. By uniting with some metals it appears to be converted into volatile alkali.
 4. *Muriatic, or spirit of sea-salt.* A volatile fluid, generally of a fine yellow colour; though this also is owing to the admixture of foreign substances, generally of iron. Inferior in power to the former, and obtained from sea-salt. Naturally this acid seems to be in an aerial state, but easily contracts an union with water. On mixture with manganese, it is wholly converted into a yellow, and almost incondensable vapour, called *dephlogisticated spirit of salt*; but which, on mixture with inflammable air, recomposes the marine acid.
 5. *Fluor acid.* Obtained from a species of spar: has little acid power, but is remarkable for its property of corroding glass.
 6. *Acid of borax, or sedative salt.* Obtained from borax in the form of scaly crystals; found also naturally in some waters in Italy, and in certain minerals in other countries.
 7. *Acetous acid.* Obtained by allowing any fermentable liquor to proceed in the fermentation till past the vinous state. It is much less corrosive, and less powerful as a solvent, than the vitriolic, nitrous, or marine acids.
 8. *Acid of tartar.* Procured from the hard substance called *tartar*, deposited on the sides of wine vessels.
 9. *Acid of sugar.* Found naturally in the juice of sorrel, and procured artificially by means of nitrous acid from sugar and a great variety of other substances. Assumes a dry form.
 10. *Acid of phosphorus.* Obtained artificially from urine, and in large quantity from calcined bones; found naturally in some kinds of lead-ore; and in vast quantities in Spain united with calcareous earth. Assumes a solid form, and melts into glass.
 11. *Acid of ants.* Procured from the animal from which it takes its name, by expression or distillation, in a fluid form.
 12. *Acid of amber.* Obtained in a solid form from amber.
 13. *Acid of arsenic.* Obtained from that substance by means of nitrous acid. Is extremely fixed in the fire.
 14. *Acid of molybdena.* Procured from that substance by means of nitrous acid. Resembles a fine white earth.
 15. *Acid of lapis ponderosus, tungsten, or wolfram.* Obtained as an acid, *per se*, from this substance by Mr Scheele; but its real acidity is denied by other chemists. Is in the form of a yellow powder.
 16. *Acid of milk.* Obtained in a fluid form from that liquor.
 17. *Acid of sugar of milk.* Obtained in form of a white powder, by means of nitrous acid, from sugar of milk.
 18. *Lithiac acid.* Obtained in a solid form from human calculus, by means of nitrous acid.
 19. *Acid of benzoin.* Obtained in a solid form from that gum by sublimation or lixiviation with quicklime.
 20. *Acid of lemons.* Obtained from the juice of that fruit by crystallization.
 21. *Sebaceous acid, or acid of fat.* Obtained in a fluid state from suet by distillation.
 22. *Acid of citrons.* Obtained in a fluid from the juice of that and other fruits.
 23. *Acid of apples.* Obtained in a fluid state from the juice of apples and other fruits.
 24. *Acid of sorrel.* Obtained in a solid form from the juice of that plant; the same with acid of sugar.

II. *ALKALIES.* These turn syrup of violets green, and with acids form neutral salts. They are,

1. *Fixed vegetable, or Pot-ash.* Always obtained from the ashes of burnt vegetables. A deliquescent salt.
2. *Fixed fossile.* A solid crystalline salt, sometimes found native, as the natrum of Egypt; and sometimes by burning seaweed as kelp.
3. *Volatile.* Obtained from sal ammoniac, from the foot of burning bodies, and from the putrefactive fermentation. It is naturally in the state of an invisible and elastic vapour, constituting a species of aerial fluid, and consists of phlogisticated and inflammable air.

ACIDS, by their union with other bodies, form

NEUTRAL SALTS.	EARTHY SALTS.	METALLIC SALTS.	ESSENTIAL SALTS.
These are always composed of an acid and an alkali, and are of many different kinds, as may be seen in the following table.	Composed of an acid joined to an earthy basis, as alum and gypsum. See the following table.	Formed of an acid and metal. The principal of these are vitriols; the others may be seen in the following table.	Obtained from vegetables, and contain an acid joined with the juices of the plant in a particular manner not to be imitated by art. To these belong sugar, manna, honey, and others of that sort.

II. EARTHS.

II. E A R T H S.

THESE are solid bodies, not soluble in water, nor inflammable; and if fused in the fire, never resume their earthy form again, but take that of glass. They are divided into *absorbent*, *crystalline*, and *argillaceous*.

I. *ABSORBENT Earths* are capable of being united with acids, and are either calcareous, or not calcareous.

a, The calcareous absorbent earths are,

1. *Limestone*, or *marble*. This is of infinite variety as to colour and texture. Marble is the hardest and finest. Those kinds of limestone which feel unctuous to the touch, are generally impregnated with clay: those that feel gritty, or where the lime is hard and weighty, contain sand; this is the best for building; the other for manure.
2. *Chalk*. A white, friable, soft substance. This is much more free of heterogeneous matters than any limestone, and is easily calcined into quicklime. It is probably nothing else than limestone suddenly concreted without being crystallized.
3. *Sea shells*, are likewise a calcareous earth, and yield a very fine quicklime. These are used in medicine.
4. *Terra ponerosa*. A fine white earth sometimes found combined with fixed air, but more commonly with the vitriolic acid; and forming with it a very heavy compound named *spatium ponderosum*. It is found in mines and veins of rocks.

b, The absorbent earths which cannot be reduced into quicklime are,

1. *Magnesia alba*. A white earth, usually found combined with the vitriolic acid, and forming bitter purging salt. It is likewise obtained from the mother-ley of nitre, the ashes of burnt vegetables, &c.
2. *Earth of alum*. A particular kind of absorbent earth, found in many places mixed with sulphureous pyrites, as in Yorkshire, &c. Clay of any kind may by a particular process be converted into this earth.
3. *Earth of animals*. This is obtained by the calcination of animal substances, and by precipitation in the process for making acid of milk. It can hardly be converted into glass; and is therefore used as a basis for white enamels, &c. It is said to consist of the phosphoric acid united to calcareous earth.

II *CRYSTALLINE OR VITRESCENT Earths*, are hard, and strike fire with steel; may be calcined in the fire; but are not soluble in acids.

Of this kind are,

1. *Sand and Flint*; found plentifully every where. With alkaline substances they are easily changed into glass; and hence are termed *vitrescent*.
2. *Precious stones* of all kinds are likewise referable to this class; but they are of a much greater degree of hardness and transparency than the others.

III. *ARGILLACEOUS Earths* are distinguished by acquiring a very hard consistence when formed into a paste with water, and exposed to a considerable degree of heat; not soluble in acids. They are,

1. *Common clay*. It is of many different colours; but chiefly red, yellow, or white. The purest is that which burns white in the fire.
2. *Medical boles*. These are of different sorts; but are only a purer kind of clay, sometimes mixed with a little iron or other matters.
3. *Lapis nephriticus*, or *steatite*. These are indurated clays, found in various parts. They are at first soft, and readily cut; but turn extremely hard in the air. Many other varieties of these earths might be mentioned; but as they do not differ in their chemical properties so much as in their external appearance, and being all mixed with one another, they more properly belong to the natural historian than the chemist.

III. METALLIC SUBSTANCES.

THESE are bodies of a hard and solid texture; fusible in the fire, and resuming their proper form afterwards; not miscible with water, nor inflammable. They are divided into *Metals* and *Semimetals*.

I. *METALS* are malleable; and the species are,

1. *Gold*. The most ponderous and fixed in the fire of all bodies except platina, and the most ductile of any. It has a yellow colour, and is more commonly found in its metallic state than any other metal. It has no proper ore; but is found in ores of silver, and almost all sands contain some of it.
2. *Silver* is next to gold in malleability and ductility; but less fixed in the fire than either it or platina. It is sometimes found in its native state; but most commonly in that of an ore with sulphur, sometimes with arsenic, and assuming different appearances.
3. *Platina*. A white metal of a greater specific gravity than gold, and altogether as fixed in the fire; the most difficult to be melted of all known substances; resisting the tests which have usually been applied for discovering the purity of gold, supposed from hence to be the *snuris* of the ancients. Found in South America.
4. *Copper*. Of a reddish colour; hard and sonorous; admits of being extended greatly under the hammer, either hot or cold. Is difficult of fusion. It is generally found in the state of an ore with sulphur. There are a great variety of ores of it, extremely beautiful, blue, red, green, and yellow.
5. *Iron*. A grey-coloured metal, extremely ductile when hot; the lightest of them all except tin. It is the only metal certainly known to admit of being welded; though platina is likewise said to possess some share of this property. It is likewise the only one capable of being tempered by cooling. It is found almost every where; and its ores are infinitely various.
6. *Tin*. A white soft metal, the lightest of the whole, and very ductile. The ores of it are generally arsenical, and assume a crystalline appearance; their colour being most usually of a dark brown, and sometimes very beautiful.

7. *Lead*. A metal of a dull bluish colour, exceedingly soft and malleable, and very weighty. Seldom found in its metallic state, but usually in an ore with sulphur or arsenic; but seldom with sulphur alone. The principal ores of it are the cubic, called *galena*, and the glassy, called *spar*.
8. *Mercury* or *quicksilver*; formerly accounted a semimetal, on account of its fluidity, but now reckoned among the most perfect metals. It is a white, opaque, metallic body; fluid, except in a very intense degree of cold; very heavy, and easily volatilized by heat. Sometimes found in its fluid form, but usually in a beautiful red ore with sulphur, called *cinnabar*.

II. *SEMIMETALS* are brittle, and do not stretch under the hammer. They are,

1. *Zinc*. A bluish white substance of a fibrous texture, considerably hard and sonorous, with a small degree of ductility; easily fused and volatilized. Its principal ore is *lapis calaminaris*.
2. *Bismuth*, or *tin-glass*. A white, ponderous, hard, brittle, and sonorous body, of a plated texture; easily fused and vitrified. It is only reduced to an ore by arsenic. Its appearance much the same with regulus of antimony.
3. *Antimony*. A blackish substance, of a fibrous needle-like texture; hard, brittle, and of a considerable weight; not difficult of fusion, and easily convertible into glass. Its only ore is with sulphur, which is the crude antimony.
4. *Arsenic*. A bright, sparkling, whitish-coloured semimetal; of a plated texture; very brittle, and extremely volatile. It is generally found in the ores of other metals.
5. *Cobalt*. A brittle semimetal fusible in a moderate heat, and easily convertible into a beautiful blue glass called *smalt*. It is always obtained from an arsenical ore, likewise called *cobalt*.
6. *Nickel*. A reddish white substance, of a close texture, and very bright; easily melted, but very difficult to vitrify.

IV. INFLAMMABLE SUBSTANCES,

Are those which continue to burn of themselves when once set on fire. They are divided into *oils*, *sulphur* or *brimstone*, *alcohol* or *ardent spirits*, and *charcoal*.

I. *OILS* are thickish, viscous fluids, not miscible with water. Divided into *animal*, *vegetable*, and *fossile*.

a, b, The animal and vegetable oils are,

1. *Expressed*. These are of a mild and bland taste, inodorous, and not soluble in alcohol. They are obtained by expression, as oil of olives, rape-seed, almonds, &c. Animal fats are of the same nature, as is also wax.
2. *Essential*. These are always obtained by distillation, possess the taste and flavour of the subject from whence they are drawn, and are soluble in alcohol. Of this kind are oil of cloves, spike, &c. The oil of ants is an example in the animal kingdom.
3. *Empyreumatic*. These are obtained by a considerable degree of heat, and possess an acrid taste and burnt-like flavour, as oil of hartshorn. They are soluble in spirit of wine.

c, *Fossile oils*. These are found in the earth in their native state; and are called, when pure, *naphtha*; which is of an acrid taste, and extremely volatile, not miscible with alcohol. A great many inflammable fossils contain this, as bitumens, pit-coal, &c.

II. *SULPHUR* or *BRIMSTONE*. This is a dry friable substance, not miscible with water. It is found in many mineral substances, metallic ores, &c. but is for the most part met with in pyrites. Great quantities of it are found in the neighbourhood of volcanoes.

III. *ALCOHOL* or *ARDENT SPIRITS*. This is a fluid of an acrid and volatile nature, miscible with water; obtained from fermented vegetable juices by distillation; as from the juice of the grape, malt-liquors, rice, &c.

IV. *CHARCOAL*. The residuum of most inflammable matters after undergoing distillation with a strong fire. A black substance, acted upon with difficulty by acids; soluble in *hepar-sulphuris*, and entirely dissolvable into inflammable air by a very violent heat. Of great use as fuel, and essentially necessary in metallurgy and other arts.

V. WATER.

A colourless insipid fluid well known. It is either *simple* or *mineral*.

I. *SIMPLE*, or *pure rain-water*, as it is called, though the most homogeneous fluid of this kind with which we are acquainted, is not perfectly pure, but always contains a portion of mucilaginous matter, which can never be perfectly separated. It is supposed to consist of dephlogisticated and inflammable air condensed.

II. *MINERAL waters* are these spring-waters impregnated with saline substances; the diversity of which is exceeding great; but they all agree in having an acid joined with them. The most common sorts are impregnated with iron and sulphur.

VI. AIR.

An invisible and permanently elastic fluid, is of the following kinds: *Dephlogisticated*, *phlogisticated*, *fixed* or *fixable*, *inflammable*, *nitrous*, *vitriolic acid air*, *marine acid air*, *dephlogisticated marine acid*, *alkaline air*, *hepatic air*, *atmosphpherical air*.

1. *Dephlogisticated*. An elastic fluid naturally extricated in the process of vegetation; artificially procured from nitre, minium, manganese, water, &c. eminently capable of supporting flame and animal life. One of the component parts of our atmosphere.

2. *Phlogisticated*. Produced in great quantities during the putrefactive fermentation; obtained also in the calcination of metals and other phlogistic processes. Destroys animal life, and extinguishes flame, but is very friendly to vegetation. Is another of the component parts of our atmosphere.
3. *Fixed, or fixable*. Has its name from the property of adhering to certain bodies, and fixing itself in them. Consists of dephlogisticated air united to charcoal. Is obtained by fermentation, and in all phlogistic processes. Manifests the properties of an acid: extinguishes flame, and destroys animal life.
4. *Inflammable*. Consists wholly of charcoal and a little water rarefied by heat; is remarkable for being the lightest of all gravitating substances. Is produced naturally in mines, and from putrid waters; artificially procured from certain metallic solutions, by passing the steam of water over red-hot iron; by distilling wood, pit-coal, &c. with a strong heat; or by exposing charcoal to the heat of a burning lens *in vacuo*. It extinguishes flame unless it be mixed with a certain proportion of atmospherical or dephlogisticated air; in which case it explodes violently, destroys animal life, but is friendly to vegetation.
5. *Nitrous*. Procured artificially in dissolving metallic or other substances in the nitrous acid. On mixture with dephlogisticated air both the fluids lose their elasticity, and a small quantity of nitrous acid is produced. It instantly kills animals, and extinguishes flame. By union with some metals is converted into volatile alkali. In some cases it may be made to support flame, and even animal life. Its property of condensing along with dephlogisticated air renders it a test of the salubrity of the atmosphere.
6. *Vitriolic acid air*. The same with volatile or sulphureous vitriolic acid.
7. *Marine acid air*. The same with marine acid reduced into vapour, and deprived of most of its water.
8. *Dephlogisticated marine acid*. Supposed by some to be the marine acid deprived of its phlogiston; by others, to be the same acid with an addition of pure air. It destroys many kinds of colours; whitens linen, and with inflammable air regenerates common marine acid.
9. *Alkaline air*. The same with pure volatile alkali; is formed by an union of phlogisticated and inflammable air.
10. *Hepatic air*. Produced from the decomposition of liver of sulphur by acids, or in the common atmosphere. It is inflammable, but does not burn with explosion.
11. *Atmospherical air*. Composed of dephlogisticated and phlogisticated air; and thus supports both animal life and vegetation.

TABLE, showing the several Combinations that the SIMPLE CHEMICAL ELEMENTARY BODIES admit of with one another; the Compound resulting from that Mixture; and the Manner in which the Union is effected: With some Account of the principal Uses to which these are applied in Arts or Manufactures.

N. B. This mark *, put above any word, denotes that there is some difficulty in the process, or that the union is not very complete.

VITRIOLIC ACID may be combined with the following Substances, viz.

ACIDS.

- { NITROUS ACID. A mixture which readily inflames oils. By solution, generating heat.
- { MURIATIC, VEGETABLE, and all other ACIDS yet known. By solution, generating heat. But these mixtures are applied to no particular use in medicine or arts.

ALKALIES.

- { *Vitriolated tartar*. By solution and crystallization, or double elective attraction from a great variety of bodies.
- { VEGETABLE. *Nitrum vitriolatum*. A vitriolated tartar, obtained by distilling from nitre with the vitriolic acid.
- { *Sal polychrestum*. By deflagrating nitre with sulphur. There are many other kinds of vitriolated tartar, known formerly by different names, and supposed to be possessed of particular properties, but they are now neglected.
- { FOSSILE. *Glauber's salt*. By solution and crystallization. Much used in medicine as a gentle purgative.
- { VOLATILE. *Secret ammoniac*. By solution. Formerly supposed a most powerful menstruum for metals, &c. but without any just foundation.

EARTHS.

- { A corroded calx. By simple corrosion. This when perfectly edulcorated with water is found to be a true gypsum.
- { *Selenites*. By precipitation from a very dilute solution of chalk in the nitrous acid, by means of the vitriolic acid.
- { CALCAREOUS EARTHS. *Terra ponderosa*. With this it unites in preference to alkalies, forming a very heavy and insoluble substance called *spatum ponderosum*.
- { *Gypsum or Paris-plaster*. Often found in a native state. May be artificially formed by precipitating from a solution of chalk in a very concentrated nitrous acid. Used as a cement; for taking impressions from medals, &c.
- { *Talc, asbestos, &c.* A native production which cannot be perfectly imitated by art. Used for holding objects in microscopes, making incombustible cloth, &c.
- { MAGNESIA. *Epsom, or magnesia Glauber's salt*. By solution and crystallization. Much used in medicine for the same purposes as real Glauber's salt.

EARTHS.

EARTHS.

EARTH of ALUM. *Alum.* By solution, crystallization, &c. Used by dyers as a preparatory for taking on the colours, papermakers, goldsmiths. &c.

EARTH of ANIMALS, OSTEOCELLA, &c. By solution. The mixtures of these are not applied to any particular use.

CLAY* *Alum.* By digesting pure clay for some time in this acid, and exposing it for some time to the air, an alum is produced; and if the clay is precipitated from this aluminous concrete, it is found to be a pure earth of alum, soluble in all acids.

FLINT. A thickish coagulum. By digesting the liquor filices in the vitriolic acid.

GOLD*. Imperfectly. By a particular process after being separated from aqua-regia.

SILVER*. By solution, after it has been precipitated from the nitrous acid by alkalies. The fumes which arise in this solution are inflammable.

COPPER. *Blue vitriol.* This is sometimes a native production, but in this way it is never pure. It is artificially prepared by solution in a very concentrated acid, and crystallizing it.

Green vitriol or copperas. Obtained at large by particular process from pyrites; or by solution, &c. in a diluted acid. This is the basis of all black dyes, ink, &c. as it strikes a black colour with vegetable astringents.

METALS.

IRON. *Salt of steel.* By calcining the crystals of green vitriol till they are converted into a white powder.

Colcothar of vitriol. By continuing the calcination till it assumes a brown colour.

LEAD. *Saturnus vitriolicus.* A solution in a boiling heat, but is again precipitated when cold.

An indissoluble concrete. By precipitation from the nitrous acid.

TIN. *Jupiter corrosivus.* By a boiling heat in a concentrated acid.

MERCURY. *Ignis Gehenne*, or infernalis of Paracelsus. By a boiling heat, and repeated coctions with fresh acid when it is evaporated.

Turpeth mineral, or mercurius precipitatus flavus. By evaporating to dryness, and then washing with water.

ANTIMONY*. *A metallic salt.* By elective attraction from butter of antimony.

SEMIMETALS.

ZINC. *White vitriol.* Often found in its native state. Artificially made by solution and crystallization in a diluted acid. Used by painters for drying.

BISMUTH. A corroded calx. By solution in a concentrated acid.

ARSENIC. - - - By ditto.

COBALT. A rose-coloured mixture. By solution. If this is precipitated by a fixed alkali, and again dissolved, the liquor appears of a beautiful red.

EXPRESSED. A blackish gummy-like mass. By solution, generating a considerable heat. Native gums are supposed to owe their origin to a mixture of this kind.

OILS.

ESSENTIAL. A dark-coloured resinous mass. A great heat and violent effervescence being produced by this mixture. Native resins supposed the same.

EMPYREUMATIC. Little known. By solution.

FOSSILE. A substance resembling amber. By solution.

SULPHUR*. Here there is no proper union of substances; but if sulphur is boiled in this acid, it becomes less inflammable and more fixed than any ordinary sulphur.

Vitriolic ether. By careful solution and distillation, the ether being separated by the addition of water.

Spiritus vitrioli dulcis. By solution and distillation.

ALCOHOL.

Oleum dulce. By continuing the heat after the ether has arisen.

Oleum anodynum minerale. By redistilling the residuum of the last with alcohol. A medicine much celebrated by Hoffman.

Sulphur. By pushing the heat after the oil comes over. It is to be observed that this is produced in every combination of this acid with inflammables or metals.

WATER. An acidulated water. Sometimes, though seldom, found issuing along with native springs. Applied to no particular use.

NITROUS ACID may be combined with the following Substances, viz.

ACIDS.

VITRIOLIC, as above.

MURIATIC. *Aqua regia.* By solution. This is the only proper menstruum for gold; and it is a solution of tin in this menstruum which is the basis of the scarlet dye.

VEGETABLE, and all others. By ditto. These compounds have no particular names, nor are applied to any particular uses in medicine or arts.

ALKALIES.

VEGETABLE. *Common nitre.* A native production. Made artificially by solution and crystallization. This deflagrates with oily or metallic bodies, and is the foundation of gun-powder.

FOSSILE. *Cubic nitre.* By solution.

VOLATILE. *Nitrous ammoniac.* By solution. This differs from all the other ammoniacal salts, by being soluble in alcohol.

Deliquescent crystals. By ditto and crystallization.

Calcareous. *Balmain's phosphorus.* By ditto and evaporating to dryness.

EARTHS.

EARTH of ALUM, and all other absorbent earths. The compounds have no names nor any remarkable properties hitherto discovered.

CRYSTALLINE EARTHS*. By solution after precipitation from the liquor filices.

METALS.

- GOLD***. *Slightly impregnated*. By a boiling heat in close vessels, after the ordinary method of separating silver from gold by the nitrous acid. It spontaneously subsides in the air.
- SILVER.** { *A fluid solution*. By solution. This when diluted with water stains hair and bones black; as also marble, agate, jasper, &c. of different colours.
Sal metallorum. By solution and crystallization.
Catharticum lunare, lunar caustic, or lapis infernalis. By inspissating the solution to dryness.
- COPPER.** A green-coloured solution. By solution.
- IRON.** A greenish solution, if a diluted acid is employed; if otherwise, it is of a yellowish colour: evaporated to dryness, it deliquesces in the air.
- LEAD.** { *A yellow solution*. By dissolving in a diluted acid. If much water is added, the metal is precipitated.
Saturni fulminans. By inspissating the solution. This explodes when put upon the fire with greater force than nitre, and has been proposed to be used as an ingredient in gun-powder to augment its force.
- TIN.** A solution or corroded calx. By a careful solution without heat it remains suspended; if otherwise, it falls down in form of a calx. This is commonly supposed to be the composition used in dyeing scarlet; but by mistake: for it is a solution of tin in aqua-regia that communicates that fine colour to cochineal. The same solution is the basis of the powder which tinges glass of a ruby colour. It is the precipitate of gold from aqua-regia by means of tin.
- MERCURY.** { *A limpid solution, intensely corrosive*. By solution.
Red precipitate. By evaporating the solution to dryness, and then calcining till it becomes red.
Mercurius corrosivus fusus. By precipitating from the nitrous acid by fixed alkali.
White precipitate. By ditto with the volatile alkali.
- BISMUTH.** { *A greenish solution*. By using a concentrated acid. This might be applied in some cases in the art of dyeing; but is not yet come into general use.
Magistery of bismuth. By precipitating from the solution by means of water. This has been employed as a cosmetic, but is inefficacious and unsafe. If mixed with pomatum, this stains hair of a dark colour without injuring it.
- ZINC.** A corroded solution. By the ordinary means.
- SEMIMETALS.** { *A colourless calx*. By simple corrosion.
Bezoardic mineral. By distilling from butter of antimony, after having added the nitrous acid.
Antimonium diaphoreticum. By adding nitre to crude antimony, and deslagrating.
Cerusa antimonii. By deslagrating regulus of antimony with nitre.
- COBALT.** { *A red liquor*. By solution either in its calcined or metallic state.
Rose-coloured crystals. By adding muriatic acid, and allowing it to crystallize.
Green sympathetic ink. By dissolving these crystals in water. The solution is red when cold, and green when warm; when wrote with, it disappears when dry; but when held to the fire it becomes green, and again disappears when cold.
- NICKEL.** A green-coloured liquor. By solution.
- OILS.** { **EXPRESSED.** A thick bituminous-like substance. Upon the mixture a considerable degree of heat is generated, and sometimes, though very seldom, actual flame is produced.
ESSENTIAL. Ditto. A more violent heat is generated upon the mixture with these oils than any other, and with many of them an actual flame is produced.
EMPYREUMATIC. This mixture has no name, nor is it applied to any remarkable use in arts.
FOSSILE. Ditto.
- ALCOHOL.** { *Nitrous ether*. By digesting; the ether arising to the surface.
Spiritus nitri dulcis. By digesting a little, and then distilling.
Acidulated water. By solution.
- WATER.**

The MURIATIC ACID may be combined with the following Substances, viz.

ACIDS.

- { **VITRIOLIC, and NITROUS.** As in the former part of this Table.
VEGETABLE, and all others yet known. By solution: but as none of these mixtures are applied to any particular purpose, we take no notice of them.

ALKALIES.

- { **VEGETABLE.** *Digestive salt*. By solution and crystallization.
FOSSILE. { *Common salt*. Commonly obtained by evaporating sea-water to dryness; or artificially made by mixing the acid and alkali, and crystallizing.
Sal gem. A native fossile salt, found in mines in Poland, Spain, &c. of the same nature as common salt, but more pure.
VOLATILE. *Common ammoniac*. Obtained at large by a particular process from foot. Artificially made by mixing the acid and alkali, and crystallizing.

EARTHS.

- { **CALCAREOUS.** { *Liquid shell*. By solution. A substance whose effects in medicine have been greatly extolled.
Ol. calcis per deliquium. By evaporating liquid shell to dryness. It naturally deliquesces.
Fixed ammoniac. By solution and crystallization. This sometimes appears luminous in the dark when struck with a hammer.
OSTEOCELLA, MAGNESIA, and other absorbents. By solution: but the properties or uses of these are not known.

METALS.

METALS.

- GOLD*. *A yellow liquor.* By boiling a calx of gold (in whatever way obtained) in this acid. It does not act upon it in its metallic state.
- SILVER*. { *A fluid solution.* By dissolving the ore of silver in this acid. It does not act upon pure metallic silver.
 Luna cornea. By elective attraction from the nitrous acid.
- PLATINA*. *A fluid solution.* With difficulty effected, after having been precipitated from aqua regia by alkalies.
- COPPER. *A green deliquescent inflammable salt.* By solution and inspissating to dryness.
- IRON. *Tinctura martis aurea.* By solution. The iron is in some measure rendered volatile by this operation.
- LEAD. { *A limpid solution.* By a boiling heat, and frequent cohobations with fresh acid.
 Cornea Saturni. By precipitation from the nitrous acid.
- TIN*. { *A corroded powder.* By simple corrosion.
 Butter of tin. By distilling from corrosive sublimate.
- MERCURY*. { *A colourless crystalline mass, extremely acrid.* By corrosion, employing the fumes of a very concentrated acid.
 Mercur. corrosiv. albus. By precipitation from the nitrous acid.
 Corrosive sublimate. By subliming from sal ammoniac, common salt, or many other bodies.
 Mercurius dulcis. By resubliming corrosive sublimate with more quicksilver.
 Mercurial panacea. By subliming corr. sub. nine times, and digesting for some time in spirit of wine.
- BISMUTH*. *A solution very slightly impregnated.* By employing a very concentrated acid.
- ZINC. *A solution of a very slight yellow colour.*
- ARSENIC*. *Butter of arsenic.* By distilling corrosive sublimate with arsenic; the arsenic uniting with the acid, and leaving the mercury.
- COBALT. *A reddish solution.* By the ordinary means. It becomes green by a gentle heat.
- NICKEL. *A green solution.* By the ordinary means.
- OILS*. By solution. The union here is but imperfect, nor have they any particular name.
- ALCOHOL. *Spiritus salis dulcis.* By digestion, and afterwards distilling. The acid here is never totally dulcified.
- WATER. *Acidulated water.* Generating heat by mixture.

VINEGAR may be combined with the following Substances, viz.

ACIDS.

VITRIOLIC, NITROUS, and MURIATIC, as in the above table. It likewise unites with all other acids, generating heat; but the properties or uses of these are not known.

ALKALIES.

- VEGETABLE. *Regenerated tartar.* By solution and crystallization.
- FOSSILE. *Polychrest of Rochelle.* By ditto.
- VOLATILE. *Spiritus Mindereri.* By solution.

EARTHS.

- CALCAREOUS EARTHS. *Earthy salts.* Not known in medicine or arts.
- MAGNESIA. *Dr Black's purging salt.* By solution. It unites with all the other absorbent earths; but the properties of these mixts are unknown.

METALS.

- COPPER. *Verdegris.* By solution and crystallization; or at large, by stratifying copper plates with the husks of the grape.
- IRON. *Sal martis aperiens.* By solution and crystallization.
- LEAD. { *Ceruse.* By exposing, in certain circumstances, thin plates of lead to the fumes of vinegar.
 Saccharum Saturni. By solution and crystallization.
- TIN*. This is not properly dissolved; but the acid is evidently impregnated. By the ordinary means of solution.
- MERCURY*. { *A fluid solution.* By employing a precipitate of mercury from the nitrous acid by alkalies.
 A red calx. By long digestion with fluid mercury.
- ZINC. *A colourless solution of a sweetish taste.* By digesting for some time.
- ANTIMONY*. *Vinum benedictum.* This is not a proper solution of the metal, but the acid is impregnated with an emetic quality.
- ARSENIC. *Vinum arsenicum.* By ditto. A curious phosphoric liquor.
- BISMUTH. *An austere styptic liquor.* By strong coction.

OILS*.

The union here is imperfect, nor have any of them obtained particular names.

ALCOHOL.

A mixture much used for anointing sprains, &c.

WATER. *Acidulated water.*

ACID OF TARTAR may be combined with the following Substances, viz.

ALKALIES.

- VEGETABLE. { Cream of tartar with excess of acid.
 Soluble tartar, when completely saturated.

ALKALIES.

- FOSSILE. Rochelle salt.
- VOLATILE. { A salt very difficult of solution with excess of acid.
 A beautiful and soluble salt when perfectly saturated.

EARTH.

EARTH. CALCAREOUS. An indissoluble selenite.
 METALS. { COPPER. A fine green colour for painting.
 { IRON. A green astringent liquid. Chalybeated tartar.
 SEMIMETAL. REGULUS of ANTIMONY. Emetic tartar.

ACID of URINE may be combined with the following Substances, viz.

ACIDS of all kinds. The nature of these not known.

ALKALI. { FIXED VEGETABLE. A salt not easily crystallized, the nature of which is not known.
 { FOSSILE. A fine crystallized salt used in medicine.
 { VOLATILE. A glass-like saline substance called *microcosmic salt*. The acid is always found in this state by evaporating urine.

VITRESCENT EARTHS. Glass of different sorts. By fusion.

METALS. { LEAD. An inflammable malleable mass. By calcining the dry salt with lead.
 { TIN. A mass resembling zinc; and inflammable. By ditto.
 { IRON. { A true *phosphorus*. By ditto.
 { A bluish solution. By employing a watery solution of the acid.
 COPPER. A corroded powder, or green solution. By a boiling heat in a watery solution of the acid.
 MERCURY. A semi-opaque mass. By fusion with the acid in its solid form.
 { ZINC. { A corroded powder, soluble in water. By solution in the acid in a watery situation.
 { A true *phosphorus*. By fusion with the dry acid.
 SEMIMETALS. { ANTIMONY. { A solution in the ordinary way.
 { A brilliant striated mass. By fusion with the dry acid.
 BISMUTH. A mixture but little changed in appearance from ordinary bismuth. By fusion.
 ARSENIC. A whitish semitransparent deliquescent mass. By fusion.
 COBALT. A reddish tincture. By solution.

OILS. *Baldwin's phosphorus*. By distilling with substances that contain oils or inflammable matters.

FLUOR ACID may be combined with the following Substances, viz.

ALKALIES. { FIXED VEGETABLE. A gelatinous saline mass which cannot be crystallized. Great part of it is also diffused by evaporation to dryness.
 { FOSSILE. A substance similar to the foregoing.
 { VOLATILE. Lets fall a quantity of siliceous earth, and forms a crystallizable ammoniacal salt.
 EARTHS. { LIME. }
 { MAGNESIA. } A gelatinous matter.
 { EARTH of ALUM. }
 { SILICEOUS EARTH. After long standing, crystals of quartz.
 METALS. { SILVER. } The calces of these metals partially dissolved; but the properties of the solution unknown.
 { QUICKSILVER. }
 { COPPER. The calx easily soluble, and affording blue crystals; the metal only partially so.
 { IRON. Dissolved with violence with the emission of inflammable vapours into an uncrystallizable liquor.

ACID of SUGAR may be combined with the following Substances, viz.

ALKALIES. { FIXED VEGETABLE. A salt scarce capable of crystallization when perfectly neutral.
 { FOSSILE. A salt difficultly soluble in water.
 { VOLATILE. An ammoniacal salt shooting into quadrangular prisms.
 EARTHS. { LIME. A kind of selenite from which the acid cannot be separated but by a burning heat.
 { TERRA PONDEROSA. A salt formed into angular crystals, scarce soluble in water.
 { MAGNESIA. A white powder insoluble without an excess of acid.
 { EARTH of ALUM. A yellow pellucid mass incapable of crystallization, and liquefying in the air.
 METALS. { GOLD. }
 { SILVER. } The calces of all these metals dissolved, but the nature of the solutions unknown.
 { PLATINA. }
 { QUICKSILVER. }
 { IRON. Dissolved in great quantity, and forming a yellow prismatic salt easily soluble in water.
 SEMIMETAL. COBALT. A yellow-coloured salt forming a sympathetic ink with sea-salt.
 INFLAMMABLES. ALCOHOL. An ether which cannot easily be set on fire unless previously heated, and burning with a blue flame.

ACID of BORAX, or SEDATIVE SALT, may be combined with the following Substances, viz.

ALKALIES. { FOSSILE. Borax. A native substance, which may be imitated by art. It is of great use in promoting the fusion of metals and earths.
 { VOLATILE. An ammoniacal salt shooting into small crystals, and melting by an intense heat into a greyish-coloured glass.
 EARTHS. { MAGNESIA. A salt crystallizable in vinegar and acid of ants. Decomposed by other acids and spirit of wine.
 { EARTH of ALUM. In certain proportions a salt difficult of solution; in others a hard mass resembling pumice-stone, yet partially soluble in water.

METAL.

METAL.

IRON. An amber-coloured solution yielding crystals of a yellow colour.

SEMIMETAL.

ARSENIC. A crystallizable compound shooting into pointed ramifications, or forming a greyish, white, or yellow powder.

ALCOHOL.

A solution with a considerable heat, which burns with a green flame.

WATER.

A solution in a considerable heat. The other mixtures with this acid not known.

ACID OF AMBER may be combined with the following Substances, viz.

ALKALIES.

{ FIXED VEGETABLE. A transparent and crystallizable salt, but deliquescent.

{ FOSSILE. A crystallizable salt not deliquescent.

{ VOLATILE. An ammoniacal salt shooting into acicular crystals.

EARTHS.

{ LIME. A crystallizable salt, difficult of solution and not deliquescent. Decomposed by common sal ammoniac.

{ MAGNESIA. A gummy deliquescent saline mass, not crystallizable.

{ EARTH OF ALUM. A prismatic salt incapable of decomposition by alkalies.

METALS.

{ SILVER. A salt shooting into thin oblong crystals obtained from the precipitate; but no solution of the perfect metal.

{ COPPER. A crystallizable salt of a green colour.

{ IRON. A crystallizable salt of a brown colour.

{ TIN. A crystallizable salt from the precipitate, scarce to be decomposed by alkalies.

{ LEAD. A crystallizable salt from the precipitate.

SEMIMETALS.

{ ZINC. A crystallizable salt.

{ BISMUTH. A crystallizable salt from the precipitate, not to be decomposed by alkalies.

{ REGULUS OF ANTIMONY. A solution of the precipitate.

ACID OF ANTS may be combined with the following Substances, viz.

ALKALIES.

{ FIXED VEGETABLE. A crystallizable salt, deliquescent in the air.

{ FOSSILE. A salt of a similar nature.

{ VOLATILE. An ammoniacal liquor, crystallizable with difficulty.

EARTHS.

{ CHALK OR CORAL. A crystallizable salt which does not deliquesce.

{ MAGNESIA. A saline liquor scarcely crystallizable.

{ TERRA PONDEROSA. A crystallizable salt which does not deliquesce.

{ EARTH OF ALUM. Unites with difficulty, and scarcely to the point of saturation. The nature of the compound not known.

METALS.

{ SILVER*. By solution. The calx of silver precipitated from aquafortis by alkalies; but does not act upon it in its metallic state.

{ COPPER. Beautiful green crystals. By dissolving and crystallizing calcined copper. It acts slowly upon it in its metallic state.

{ IRON. A crystallizable salt. It dissolves this metal with great facility.

{ LEAD*. A salt resembling saccharum saturni. By dissolving the red calx of lead. But it does not act upon it in its metallic state.

SEMIMETAL.

{ ZINC. Elegant crystals. By the ordinary means.

The effects of this acid upon other bodies, or the uses to which these combinations might be applied, are not yet sufficiently known.

ACID OF ARSENIC may be combined with the following Substances, viz.

ALKALIES.

{ FIXED VEGETABLE. A ponderous salt shooting into fine crystals by supersaturation with acid.

{ FOSSILE. A salt crystallizable when perfectly neutral.

{ VOLATILE. A peculiar kind of ammoniacal salt parting with the alkali, and decomposing some of it in a strong fire.

EARTHS.

{ CHALK. A crystallizable salt scarcely soluble.

{ MAGNESIA. A gelatinous mass which cannot be crystallized.

{ TERRA PONDEROSA. An insoluble white powder.

METALS.

{ COPPER. A green-coloured solution.

{ IRON. A very thick gelatinous solution.

{ LEAD. A solution which cannot be crystallized.

{ TIN. A gelatinous solution in the moist way. A mixture taking fire in close vessels in the dry way.

{ ZINC. A solution in the moist way, and in the dry, a mixture taking fire in close vessels.

SEMIMETALS.

{ BISMUTH. A partial solution.

{ REGULUS OF ANTIMONY. A partial solution.

{ COBALT. A partial solution of a red colour.

{ MANGANESE. A partial solution in its natural state. When the manganese is phlogisticated, a crystallizable salt may be obtained.

INFLAMMABLES.

{ CHARCOAL. A mixture taking fire and subliming when heated in close vessels.

{ OIL OF TURPENTINE, &c. A thick black substance after some days digestion.

{ SULPHUR. A red sublimate.

ALKALIES

	TIN. A corroded powder. By the ordinary means of solution.
	COPPER. By ditto.
METALS.	LEAD. A fluid solution. By ditto. This stains hair black.
	IRON*. A blood-coloured solution. By dropping a solution of iron in the nitrous acid, into an alkaline lixivium.
	MERCURY*. A fluid solution. After precipitating it from acids; if the alkali is in too large proportions, it then dissolves it, especially if the alkali has been calcined in contact with the flame.
	ZINC*. By solution, after having precipitated it from the nitrous acid.
	BISMUTH*. By solution, after having precipitated it from the nitrous acid.
	<i>Kermes mineral.</i> By dissolving antimony in an alkaline lixivium, filtering, and allowing it to stand in a cool place till it precipitates.
	<i>Golden sulphur of antimony.</i> By dissolving a crude antimony in an alkaline lixivium, and precipitating by an acid.
SEMIMETALS.	ANTIMONY. <i>Hepar antimonii.</i> By deflagrating crude antimony with nitre.
	<i>Crocus metallorum.</i> Is hepar antimonii pulverised and edulcorated with water.
	<i>Diaphoretic antimony.</i> By deflagrating regulus of antimony with nitre.
	<i>Antimoniated nitre.</i> By dissolving diaphoretic antimony in water, and allowing it to crystallize.
	<i>Magistery of antimony.</i> By precipitating a solution of diaphoretic antimony by adding vinegar.
	<i>Regulus antimonii medicinalis.</i> By fusing crude antimony with alkali. This is not properly a compound of alkali and antimony, but of another kind. But as it is a term much used, it was proper to explain it.
	ARSENIC*. A metallic arsenical salt. By a particular elective attraction from regulus of antimony and nitre.
	EXPRESSED. Soap. The best hard soap is made of olive-oil and fossile alkali. The ordinary white soap of this country is made of tallow and potash; black soap with whale-oil and potash.
OILS.	ESSENTIAL. Saponaceous mass. Best made by pouring spirit of wine upon caustic alkali and then oil, digesting and shaking.
	EMPYREUMATIC. This mixture dissolves gold when precipitated from aqua regia; and is the basis of the fine colour called <i>Prussian blue</i> ; and has various other properties, as yet but little known.
	FOSSILE. This has no name, nor are the properties well known; but from some observations that have been made on native soapy waters, it is probable that it would keep linen much longer white than any other kind of soap.
SULPHUR.	<i>Hepar sulphuris.</i> By injecting alkalies upon melted sulphur.
WATER.	<i>Lac sulphuris.</i> By dissolving sulphur in an alkaline lixivium, and precipitating by an acid.
	Alkaline lixivium, when caustic, or even the ordinary solution of mild alkali, is a fluid of great power in washing, blacking, &c.
AIR.	FIXED. Mild alkali. This is the general state in which alkalies are found; but if they are rendered caustic by means of quick-lime or otherwise, they again absorb it from the air, or from many other bodies, by elective attraction. When perfectly mild, this alkali may be made to assume a crystalline form.

The VOLATILE ALKALI, or SPIRIT OF SAL AMMONIAC, can be united with these Bodies, viz.

ACIDS: Vitriolic, Nitrous, Muriatic, Vegetable; of Urine, of Amber, of Ants, &c.

ALKALI, as above.

	GOLD*. { <i>Aurum fulminans.</i> A powder obtained by precipitating it from aqua regia by volatile alkalies.
	{ A liquid solution. By adding a large proportion of alkali after it has been precipitated from aqua regia. This deposits the gold when long exposed to the air. The curious vegetation called <i>arbor Diana</i> is formed by adding mercury to this solution. A violently fulminating powder obtained by digestion.
	SILVER*. A solution. After it has been precipitated from the nitrous acid. A fulminating powder by digestion.
	PLATINA*. By solution, after having precipitated it from aqua regia.
METALS.	{ A blue-coloured solution. By the ordinary means. This when evaporated to dryness, and mixed with tallow, tinges the flame green.
	COPPER. { Sapphire-coloured crystals. By crystallizing the solution.
	{ <i>Venus fulminans.</i> By evaporating the solution to dryness.
	{ <i>Aqua cerulea sapphirina.</i> By mixing sal ammoniac, quick-lime, and thin plates of copper, with water, and allowing them to remain a night.
	IRON. By ordinary solution.
	LEAD. By ditto.
	TIN. The mixts that are produced by these metals are little known.
	BISMUTH*. By solution, after having precipitated it from the nitrous acid.
SEMIMETALS.	ANTIMONY.
	COBALT. A reddish liquor. By solution.
	NICKEL. A blue liquor. By ditto.
	EXPRESSED. Has no name. By solution.
	ESSENTIAL. <i>Sal volatile oleosum.</i> By ditto with some difficulty, unless the alkali is in a caustic state.
OILS.	EMPYREUMATIC. A pungent oily substance, of great power in medicine. The principal one of this kind in use is spirit of hartshorn.
	FOSSILE. A particular kind of soapy substance.

- SULPHUR.** Smoking spirit of sulphur. By distilling sal ammoniac, quick-lime, and sulphur.
ALCOHOL*. By distilling alcohol from volatile alkalies, it acquires a caustic fiery taste; but the union is not complete.
WATER. This solution might be of use in washing or bleaching; but, unless in particular cases, would be too expensive. It coagulates with alcohol.
AIR. **FIXED.** Mild volatile alkali. The usual state in which it is found; nor has any method yet been discovered of rendering it solid but in this state.

EXPRESSED OILS may be combined with the following Substances, viz.

- ACIDS:** Vitriolic, Nitrous, Muriatic, Vegetable, of Urine, of Amber, as in the foregoing part of this Table.
ALKALIES: Fixed and Volatile, as above.
CALCAREOUS EARTHS. A kind of plaster. By mixture when in a caustic state.
METALS. { **TIN*.** Ditto. By solution when the tin is in the state of a calx.
 { **LEAD*.** Ditto. By boiling the calx of lead in oils. This is used for cements in water-works. The common white paint is a mixture of this less perfect.
SEMIMETALS. **ZINC*.** Ditto. By ditto.
OILS: Essential, Empyreumatic, and Fossile. By mixture; but their uses are not much known.
SULPHUR. *Balsam of Sulphur.* By solution in a boiling heat.
ALCOHOL. After expressed oils are freed from soap or plasters, they are soluble in alcohol; but not in their ordinary state.

ESSENTIAL OILS may be combined with the following Substances, viz.

- ACIDS:** Vitriolic, Nitrous, &c. as above.
ALKALIES: Fixed and Volatile, as above.
METALS. { **COPPER.** By solution.
 { **LEAD.** By ditto.
OILS of all kinds. By solution or mixture.
SULPHUR. A balsam of sulphur. By solution, imperfectly; better by adding essential oils to the solution made by expressed oils or hepar sulphuris.
ALCOHOL. { Imperfect mixture. By solution.
 { Aromatic waters. By distillation.
WATER. Distilled water of the shops. By distilling recent vegetable substances with water.

EMPYREUMATIC OILS may be combined with the following Substances, viz.

- ACIDS:** Vitriolic and Nitrous, as above.
ALKALIES: Fixed and Volatile, as above.
OILS of all kinds. By mixture.
ALCOHOL. By solution. By repeated distillations the oils are rendered much more subtile.

FOSSILE OILS may be combined with the following Substances, viz.

- ACIDS:** Vitriolic and Nitrous, as above.
ALKALIES: Fixed and Volatile, as above.
OILS of all kinds. By mixture.
SULPHUR. With some difficulty, by solution.
ALCOHOL. - - - By ditto.

SULPHUR may be combined with the following Substances, viz.

- ACID*:** Vitriolic; with the phenomena above described.
ALKALIES: Fixed and Volatile, as above.

- METALS.** { **SILVER.** A mass of a red-like colour. By adding sulphur to red-hot silver, and fusing; found also with it in the state of an ore.
 { **LEAD.** A sparkling friable mass, hardly fusible. By deflagrating sulphur with lead. This in a native state forms the ore of lead called *galena*.
 { **COPPER.** A black brittle mass, easily fused. By adding sulphur to red-hot copper, or stratifying with sulphur and fusing. Naturally in some yellow pyrites.
 { A spongy-like drops, easily fusible. By putting sulphur to red-hot iron. This is also found naturally in the common yellow or brown pyrites.
 { A fulminating compound. By mixing filings of iron with sulphur, moistening them with water, and pressing them hard, they in a few hours burst out into flame. This composition has been employed for imitating earthquakes.
IRON. { *Crocus martis.* By deflagrating with iron.
 { *Crocus martis aperiens.* By calcining the crocus martis in the fire till it assumes a red appearance.
 { *Crocus martis astringens.* By pushing the heat still further.
TIN. A dark-coloured mass, resembling antimony. By fusion.
 { *Ethiops mineral.* By heating flowers of sulphur, and pouring the mercury upon it, and stirring it well. Its natural ore is called *cinnabar*.
MERCURY. { *Falitious cinnabar.* By applying the mercury and sulphur to each other in their pure state, and subliming.
 { *Cinnabar of antimony.* By subliming corrosive sublimate and crude antimony; or the residuum, after distilling butter of antimony.

SEMIMETALS.

SEMIMETALS. { **BISMUTH.** A faint greyish mass, resembling antimony. By fusion. If in its metalline state, the sulphur separates in the cold; but not so if the calx has been employed.
ANTIMONY. *Crude antimony.* By fusion.
ZINC*. A very brittle, dark-coloured, shining substance. With some difficulty, by keeping it long in a moderate fire, and covering it several times with sulphur, and keeping it constantly stirred.
ARSENIC. { *Yellow arsenic.* By fusing it with $\frac{1}{10}$ th its weight of sulphur.
Red arsenic. By ditto with $\frac{1}{5}$ th its weight of sulphur.
Ruby of sulphur, or arsenic, or golden sulphur. By subliming when the proportions are equal.
Orpiment. A natural production; not perfectly imitable by art; composed of sulphur and arsenic. Much used as a yellow paint.
NICKEL. A compound; compact and hard as lead; of a bright metallic appearance; internally yellow. By fusion.
OILS: Expressed, Essential, and Fossile, as above.
WATER. *Gas sylvestre.* By receiving the fumes of burning sulphur in water. This ought rather to be called a union of the volatile vitriolic acid with water.

ALCOHOL may be combined with the following Substances, viz.

ACIDS: Vitriolic, Nitrous, Muriatic, Vegetable, and of Borax, as above.

ALKALI*: Volatile, as above.

METALLIC calces, in some particular cases.

OILS: Expressed, Essential, Empyreumatic, and Fossile, as above.

WATER. By solution.

GOLD may be combined with the following Substances, viz.

ACIDS: Vitriolic*, Nitrous*, and Muriatic*. In the circumstances and with the phenomena above described.

ALKALIES: Fixed*, and Volatile*, as above.

METALS. { **SILVER.** By fusion. And the same is to be understood of all the combinations of metals, unless particularly specified.
PLATINA. Ductile, and of a dusky colour. This has been employed to debase gold, as it is of the same specific gravity, and is not discoverable by the usual tests for discovering the purity of gold.
LEAD. A very brittle mass. Gold is rendered pale by the least admixture with this.
TIN. A brittle mass when the tin is added in considerable quantity; but the former accounts of this have been exaggerated.
COPPER. Paler and harder than pure gold. This mixture is used in all our coins, the copper being called the alloy.
IRON. Silver-coloured, hard and brittle; very easily fused.
MERCURY. Soft like a paste called an *amalgamum*. By solution; it being in this case called *amalgamation*; and the same is to be understood of the solution of any other metal in quicksilver.
ZINC. A bright and whitish compound, admitting of a fine polish, and not subject to tarnish; for which qualities it has been proposed as proper for analysing specula for telescopes.
ARSENIC. Brittle; and the gold is thus rendered a little volatile.
SEMIMETALS. { **ANTIMONY.** A fine powder for staining glass of a red colour. By calcination.
BISMUTH*. A brittle whitish regulus; volatile in the fire.
COBALT.
NICKEL. White and brittle.

SILVER may be combined with the following Substances, viz.

ACIDS: Vitriolic*, Nitrous*, Muriatic*, Vegetable*, and Acid of Ants*, as above.

ALKALIES: Fixed* and Volatile*, as above.

CRYSTALLINE EARTHS and other vitreous matters. A fine yellow opaque glass. The finest yellow paint for porcelain is procured from a glass mixed with silver.

METALS. { **GOLD,** as above.
PLATINA. Pretty pure and malleable. Difficult of fusion; and in part separates when cold.
LEAD. Very brittle.
TIN. Extremely brittle, as much so as glass.
COPPER. Harder than silver alone. Used in small proportions as alloy in coins.
IRON. A hard whitish compound.
MERCURY*. By amalgamation with silver-leaf, or calx of silver precipitated by copper, but not by salts. This is used for silverizing on other metals, in the same way as the amalgamum of gold.
ZINC. Hard, somewhat malleable, and of a white colour.
SEMIMETALS. { **ANTIMONY.** A brittle mass.
BISMUTH. A white semi-malleable body.
ARSENIC. Brittle; the silver being rendered in part volatile.
COBALT.

SULPHUR, as above.

LEAD may be combined with the following Substances, viz.

ACIDS: Vitriolic, Nitrous, Muriatic, Vegetable, of Urine, of Ants, as above.

ALKALIES: Fixed and Volatile, as above.

CRYSTALLINE EARTHS. A thin glass. By fusion in a moderate heat.

METALS.

- GOLD and Silver, as above.
- PLATINA. Of a leafy or fibrous texture, and purplish or blue colour, when exposed to the air. If a large proportion of platina is used, it separates in the cold.
- TIN. A little harder than either of the metals, and easily fused: hence it is used as a solder for lead; and it forms the principal ingredients of pewter. If the fire is long continued, the tin floats on the surface.
- COPPER*. Brittle and granulated, like tempered iron or steel when broke. By throwing pieces of copper into melted lead. The union here is very slight.
- IRON*. An opaque brownish glass. By a great degree of heat if the iron has been previously reduced to the state of a calx; but never in its metallic state.
- MERCURY*. By amalgamation. Effected only in a melting heat, unless some bismuth has been previously united with the mercury.
- ZINC. Hard and brittle. By pouring zinc on melted lead. If the zinc is first melted, and the lead injected upon it, it then deflagrates.
- ANTIMONY*.
- BISMUTH. A grey-coloured semi-malleable body, easily fused; and thence used as a solder for lead or tin.
- ARSENIC. { A grey-coloured brittle mass, easily fused, and extremely volatile.
A hyacinth-coloured glass. By fusion in a considerable heat. This glass is easily fused; and is a much more powerful flux than pure glass of lead.
- COBALT. The nature of this compound is not known.
- NICKEL. A brittle metallic body.

OILS: Expressed* and Essential, as above.

SULPHUR, as above.

TIN may be combined with the following Substances, viz.

ACIDS: Vitriolic*, Nitrous*, Muriatic, Vegetable*, of Urine, as above.

ALKALIES: Fixed and Volatile, as above.

CRYSTALLINE EARTHS or other vitreous matters. An opaque white vitreous mass, which forms the basis of white enamels.

METALS.

- GOLD, Silver, and Lead, as above.
- PLATINA. A coarse hard metal which tarnishes in the air.
- COPPER. A brittle mass. When the copper is in small proportions, it is firmer and harder than pure tin. This, in right proportions with a little zinc, forms bell-metal.
- IRON. A white brittle compound. By heating filings of iron red-hot, and pouring melted tin upon them. A metal resembling the finest silver is made of iron, tin, and a certain proportion of arsenic.
- MERCURY. This amalgamum forms foils for mirrors; and forms the yellow pigment called *aurum mosaicum*. By being sublimed with sulphur and sal ammoniac.
- ZINC. Hard and brittle. When the zinc is in small proportions, it forms a very fine kind of pewter.
- ANTIMONY* *Regulus veneris*. By elective attraction from copper and crude antimony.
- BISMUTH. Bright, hard, and sonorous, when a small proportion of bismuth is used. This is very easily fused, and employed as a solder.
- ARSENIC. A substance in external appearance resembling zinc.
- COBALT. By fusion.
- NICKEL. A brittle metallic mass.

OIL: Expressed*, as above.

SULPHUR, as above.

COPPER may be combined with the following Substances, viz.

ACIDS: Vitriolic, Nitrous, Muriatic, Vegetable, of Urine, of Amber, of Ants, as above.

ALKALIES: Fixed, and Volatile, as above.

METALS.

- GOLD, Silver, Lead*, and Tin, as above.
- PLATINA. A white and hard compound, which does not tarnish so soon as pure copper, and admits of a fine polish.
- IRON. Harder and paler than copper. Easily fused.
- MERCURY*. A curious amalgam. Soft at first, but afterwards brittle. By triturating mercury with verdigris, common salt, vinegar, and water.
- BRASS. Commonly made by cementation with calamine. The larger the proportion of zinc, the paler, harder, and more brittle is the brass.
- ZINC. { *Prince's metal*, *pinchbeck*, and other metals resembling gold. By employing zinc in substance in small proportions. The best pinchbeck about 1-4th of zinc.
Spelter. A native substance, found in Cornwall, consisting of zinc and copper, and used as a solder.
- ANTIMONY. By fusion.
- BISMUTH. A palish brittle mass. Somewhat resembling silver.
- ARSENIC. *White copper*. By pouring arsenic, fused with nitre, upon copper in fusion. If too large a proportion of arsenic is used, it makes the compound black and apt to tarnish.
- COBALT. White and brittle.
- NICKEL. White and brittle, and apt to tarnish.

OIL: Essential, as above.

SULPHUR, as above.

IRON may be combined with the following Substances, viz.

ACIDS: Vitriolic, Nitrous, Muriatic, Vegetable, of Urine, of Amber, of Ants, as above.

ALKALIES: Fixed*, and Volatile, as above.

VITRESCENT EARTHS. A transparent glass. In general blackish; but sometimes yellow, green, or blue. The colour is influenced by the degree of heat as well as nature of the ingredients.

METALS.

{ GOLD, Silver*, Lead*, Tin, and Copper, as above,

{ PLATINA. With cast iron it forms a compound remarkably hard, somewhat ductile, and susceptible of a fine polish.

{ ZINC. A white substance resembling silver.

{ ANTIMONY. The magnetic quality of the iron is totally destroyed in this compound.

{ BISMUTH. In a strong heat, this emiteth flames.

SEMIMETALS.

{ ARSENIC. A whitish, hard, and brittle compound. By fusing with soap or tartar. A metal resembling fine steel is made by fusing cast iron with a little arsenic and glass.

{ COBALT. A compound remarkably ductile. By fusion in a moderate heat.

{ NICKEL. A brittle mass.

SULPHUR, as above.

MERCURY may be combined with the following Substances, viz.

ACIDS: Vitriolic, Nitrous, Muriatic, Vegetable*, of Urine, as above.

ALKALI: Fixed*, as above.

METALS.

{ GOLD, Silver*, Lead*, Tin, and Copper, as above.

{ PLATINA. The compound resulting from this mixture is not known.

{ ZINC. An amalgam. Soft or hard, according to the proportions employed.

SEMIMETALS.

{ ANTIMONY. By melting the regulus, and pouring it upon boiling mercury. By frequently distilling from this amalgam, the mercury is rendered much more pure, and is then called *animated mercury*.

{ BISMUTH. A silverizing for iron. By putting this amalgam upon iron, and evaporating the mercury. It has much the appearance of silver.

{ COBALT. By mixing first with nickel, and then adding mercury.

SULPHUR, as above.

ZINC may be combined with the following Substances, viz.

ACIDS: Vitriolic, Nitrous, Muriatic, Vegetable, of Urine, of Amber, of Ants, as above.

METALS.

{ GOLD, Silver, Lead, Tin, Copper, and Iron, as above.

{ PLATINA. A hard substance.

{ MERCURY, as above.

SEMIMETALS.

{ ANTIMONY. This mixture is applied to no particular use.

{ ARSENIC. A black and friable mass.

{ COBALT. The particular nature and properties of this mixt is not known.

OIL: Expressed*, as above.

SULPHUR*, as above.

ANTIMONY may be combined with the following Substances, viz.

ACIDS: Vitriolic*, Nitrous, Vegetable*, and Urinous. With the phenomena, and by the means above described.

ALKALIES: Fixed and Volatile, as above.

VITREOUS EARTHS. A thin penetrating glass; which is a powerful flux of metals.

METALS.

{ GOLD, Silver, Lead, Tin*, Copper, and Iron, as above.

{ PLATINA. A hard mass.

{ MERCURY, and Zinc, as above.

SEMIMETALS.

{ BISMUTH. A mass resembling regulus of Antimony.

{ ARSENIC. The nature and qualities of this mixt are not known.

{ COBALT. Nature unknown.

{ NICKEL. Ditto.

SULPHUR, as above.

BISMUTH may be combined with the following Substances, viz.

ACIDS: Vitriolic, Nitrous, Muriatic, Vegetable, and Urinous; with the phenomena, &c. above described.

ALKALIES: Fixed*, and Volatile*, as above.

VITREOUS MATTERS. A yellow glass. The ore of Bismuth affords with these a blue glass; but this is probably owing to some mixture of Cobalt with it.

METALS.

{ GOLD, Silver, Lead, Tin, Copper, and Iron, as above.

{ PLATINA. This mixture changes its colour much on being exposed to the air.

{ MERCURY, as above.

{ ANTIMONY, as above.

SEMIMETALS.

{ ARSENIC. Nature not known.

{ COBALT*. By mixing first with nickel or regulus of antimony, and then adding cobalt; but it cannot be united by itself.

{ NICKEL. This mixt is not known.

SULPHUR, as above.

ARSENIC may be combined with the following Substances, viz.

ACIDS: Vitriolic, Muriatic*, Vegetable*, and Urinous; with the phenomena, &c. above mentioned.

ALKALIES: Fixed, and Volatile; with the phenomena, and by the means mentioned above.

VITREOUS MATTERS. A glass which greatly promotes the fusion of other substances. The arsenic must first be prepared by dissolving and precipitating from alkalies.

METALS. { GOLD, Silver, Lead, Tin, Copper, and Iron, as above.
PLATINA.

SEMIMETALS. { ZINC, Antimony, and Bismuth, as above.
COBALT.

SULPHUR, as above. { NICKEL. The phenomena attending these mixtures have not been as yet particularly observed.

PLATINA may be combined with the following Substances, viz.

ACIDS: Muriatic*; with the phenomena, &c. mentioned above.

ALKALI: Volatile, as above.

METALS: GOLD, Silver, Mercury, Tin, Copper, and Iron, as above.

SEMIMETALS. { ZINC, Bismuth, and Arsenic, as above.
COBALT.
NICKEL. The phenomena attending these mixtures not yet observed.

COBALT may be combined with the following Substances, viz.

ACIDS: Vitriolic, Nitrous, Muriatic, and Urinous; with the phenomena, &c. as above described.

ALKALI: Volatile, as above.

EARTHS. CALX OF FLINT. { Saffre. By mixing calcined cobalt with calx of flint, and moistening them with water, and pressing them close in wooden tubs.

METALS: { Smalt. By vitrifying these with the addition of a little potash.
GOLD, Silver, Platina, Mercury*, Lead, Tin, Copper, and Iron, as above.

SEMIMETALS. { ZINC, Antimony, Bismuth*, and Arsenic, as above.
NICKEL. The properties of this compound not known.

NICKEL may be combined with the following Substances, viz.

ACIDS: Nitrous, and Muriatic; with the phenomena, &c. as mentioned above.

ALKALI: Volatile, as above.

METALS: Gold, Platina, Lead, Tin, Copper, and Iron, as above.

SEMIMETALS: Antimony, Bismuth, Arsenic, and Cobalt, as above.

SULPHUR, as above.

ABSORBENT EARTHS may be combined with the following Substances, viz.

ACIDS: Vitriolic, Nitrous, Muriatic, and Vegetable; with the phenomena, and by the assistances above mentioned.

ALKALIES: Fixed as above.

EARTHS. { CRYSTALLINE. By this mixture they are both much easier melted into glass than by themselves, but not without the addition of some alkali.

WATER. { ARGILLACEOUS. This mixture easily runs into a glass without any addition.

Lime-water. By solution. It is sometimes found flowing out of the earth in springs; and as it always quits the water when exposed to the air, it is there deposited on the banks of the streams, forming the stony incrustations called *petrifications*: And filtering through the pores of the earth, and dropping through the roofs of subterraneous caves, it forms the curious incrustations found hanging from the roof of such places; sometimes assuming forms stupendously magnificent.

AIR. FIXT. Lime-stone. It is from the quality that quick-lime has of absorbing its air, and again with it resuming its stony consistence, that it is fitted for a cement in building; and the great hardness of the cements in old buildings is owing to the air being more perfectly united with these than in newer works.

CRYSTALLINE or VITRESCENT EARTHS may be combined with the following Substances, viz.

ACIDS: Vitriolic*, and Nitrous*; with the phenomena, &c. as above mentioned.

ALKALI: Fixed, as above.

ABSORBENT EARTHS: as above.

ARGILLACEOUS EARTHS. A mass running into glass in a moderate heat.

METALS: Lead, Tin, Copper, and Iron, as above.

WATER. Although this is not soluble in water by any operation that we are acquainted with; yet, from its crystalline form, it is probable that it has been once suspended; and certainly it is so at this day in those petrifying springs whose incrustations are of the crystalline sort.

SEMIMETALS: Antimony, Bismuth, Arsenic, and Cobalt, as above.

ARGILLACEOUS EARTH may be combined with Absorbent and Crystalline Earths, as above. With water it only unites into a paste of a mechanical nature.

I N D E X.

ABSOLUTE HEAT, defined, n^o 37. Difference of the absolute heat of different fluids, 46.

Absorption of heat the universal cause of fluidity, 119. Vapour formed by the absorption of latent heat, 120.

Ascension of Homburg's pyrophorus explained, 1418.

Acetous acid, its specific gravity, 400.

This acid and its combinations particularly treated of, 867. Procured by a particular kind of fermentation, *ib.* Of its combination with alkalies, 868. With earths, 872 *et seq.* With metallic substances, *ib.* Whether tin be soluble in it, 879. Of its concentration, 881. May be crystallized in form of a salt, 882. May be reduced into an aerial form, 883. Its combination with inflammable bodies, 884. Produces a greater quantity of ether than the vitriolic acid, *ib.* Acid of milk seems to be of the acetous kind, 978. Whey may be converted into an acetous acid, 979. May be almost entirely destroyed by fire, 1001. Requisites for bringing it nearer to the state of tartar, 1002. Westrumb's unsuccessful attempt to do so, 1003. Dr Crell's opinion of the possibility of this transmutation, 1004. Method recommended by him for trying the experiment, 1005. His experiments proving that all the vegetable acids may be reduced to the acetous, 1006. *et seq.* Manganese soluble with difficulty in it, 1369. Procurable from the residuum of vitriolic ether, 2d 722. Best prepared from sugar of lead and oil of vitriol, 882. Mr Dolfuss's method of making the acetous ether readily, 884. How to prepare it from vinegar of wood, *ib.* The acetous acid has an affinity with that of ants, 1504. How to crystallize its combination with the volatile alkali, 1515. Particular description of the salts formed by combining it with calcareous earth, 1516. With magnesia, 1517. Its phenomena with zinc, 1518. With arsenic, 1519. Supposed to be an antidote against that poison, 1520. Produces a curious phosphoric liquor with it, 2d 957, 1521. Its effects on silver, 1523. Gold, 1524. Inflammable substances, 1525. Dissolves gums, gum-resins, the flesh and bones of animals, &c. *ib.* Various methods of concentrating it, 1526. Of its crystallization, 1527. Difference between common acetous acid and radical vinegar, 1528. Mr Keir's opinion concerning them, 1529. How to obtain it from *tetrafoliata tartari*, *ib.*

Aebard's method of making crucibles from the calx of platina, 587.

Acid: Phenomena attending the solution of a metal in one, 180. The nitrous most violent in its opera-

tion, 181. Vitriolic acid next to it, 182. The marine acid much weaker than either, except when dephlogisticated, 183. The other acids still weaker, 184. Why the nitrous acid precipitates a solution of tin or antimony, 200. Pure vitriolic acid cannot be reduced into an aerial state but by combination with phlogiston, 202. The nitrous acid still more remarkably changed by such a combination, 203. The marine acid capable of assuming an aerial state by reason of the phlogiston it naturally contains, 205. Table of the quantity of acid taken up by various bases, 268. The vitriolic acid contains more fire than the nitrous or marine, 278. On the expulsion of the nitrous by the diluted vitriolic acid, 280. By the same concentrated, 281. By a small quantity of dilute vitriolic acid, 282. On the expulsion of the marine acid by the concentrated vitriolic, 283. On the decomposition of vitriolated tartar by nitrous acid, 285. This salt cannot be decomposed by dilute nitrous acid, 287. Of its decomposition by marine acid, 288. Requisites for the success of the experiment, 289. Why the marine acid cannot decompose vitriolated tartar previously dissolved in water, 290. The decompositions of vitriolic ammoniac and Glauber's salt by this acid never complete, 291. Nitrous salts decomposed by it, 292. Marine salts decomposed by the nitrous acid, 293. Selenite cannot be decomposed by marine acid, and why, 294. Why the vitriolic acid resumes, on evaporation, the basis it had left, 295. An excess of acid requisite to make metals soluble in water, 297. Nitrous acid attracts silver more than fixed alkali, 301. Solution of lead in nitrous acid decomposed by salts containing the marine acid, 312. Vitriol of mercury decomposed by marine acid, 313. Precipitation of corrosive sublimate by concentrated vitriolic acid explained, 315. Of the excess of acid in the solution proper for making experiments on metallic precipitates, 334. Iron and zinc the only metals dissolved by vitriolic acid, 337. Nitrous acid dissolves all metals, though it has less affinity with them than the vitriolic or marine, 338. Why it cannot dissolve them when very concentrated, 339. In what cases marine acid can dissolve metals, and when it cannot, 340. A triple salt formed by marine acid, iron, and regulus of antimony, 366. Another by the same acid, regulus of antimony, and copper, 367. Bismuth precipitates arsenic from the nitrous acid, 369. Copper precipitates it from the marine acid, 370.

Method of finding the quantity of pure acid contained in spirit of salt, 376. In other acid liquors, 378. Quantities of acid, water, and alkali, in digestive salt, 379. Mr Kirwan's method of saturating an acid exactly with an alkali, 381. Quantity of mild and caustic vegetable alkali saturated by a given quantity of marine acid, 382. Pure nitrous acid cannot be made to assume an aerial state, 383. How to determine the quantity of pure acid in spirit of nitre, 384. Proportion of acid in spirit of nitre to that in spirit of salt, 385. To find the specific gravity of the pure nitrous acid, 386. To determine its mathematical specific gravity, 388. Of the quantity of real acid contained in it, 389. Quantity of acid, water, and alkali, in nitre, 391. Experiments on the specific gravity, &c. of vitriolic acid, 395. Dilution of the concentrated acid necessary for these experiments, 396. How to find the specific gravity of pure vitriolic acid, 397. Quantity of acid, water, and alkali, in vitriolated tartar determined, 398. Specific gravity of the acetous acid, 400. Why the precipitates of alum and mercury contain a part of the acid, 408. How to determine the quantity of pure acid in any substance, 410. Exact computation of the quantity of pure acid taken up by mild vegetable alkali, 418. Of the quantities of acid and water in spirit of nitre, 426. Quantity of pure acid taken up by various substances, 428. Quantity of vitriolic acid necessary to saturate mineral alkali, 430. Of the same alkali saturated by dephlogisticated nitrous acid, 432. By marine acid, 433. Quantity of marine acid saturated by calcareous earth, 438. Alum always contains an excess of acid, 448. Proportion of the pure earth of alum taken up by nitrous acid, 449. By marine acid, 450. Quantity of iron taken up by the vitriolic acid, 453. Why vitriolic air is produced by dissolving iron in concentrated vitriolic acid, 455. Of the solution of the calces of iron in vitriolic acid, 456. Proportion of iron dissolved by the nitrous acid, 458. Vitriolic acid acts on iron in a much more dilute state than the nitrous, 461. Proportion of this metal taken up by the marine acid, 462. Calces of iron precipitated of a reddish colour from the marine acid, 463. Of the quantity of copper dissolved in the vitriolic acid, 464. Inflammable and vitriolic air obtained by dissolving copper in this acid, 465. Why the dilute vitriolic acid will not act upon copper, 466. Quantity of copper dissolved in nitrous acid, 468. In marine acid, 469. Effects of the vitriolic acid on tin,

470. Of the nitrous acid, of the marine acid, of the vitriolic acid, on lead, 474. Of the nitrous acid, 476. Scarce soluble in dilute vitriolic acid, 475. Effects of the marine acid upon lead, 477. Of the vitriolic acid on silver, 478. Of nitrous acid on the same, 479. Of the dissolution of silver in marine acid, 480. The nitrous acid cannot, according to Mr Kirwan, dissolve gold, 484. Effects of the vitriolic acid on mercury, 485. Of the nitrous acid, 486. Of the marine acid, 2d 486. Of the vitriolic acid on zinc, 487. Of nitrous acid upon it, 488. Less of this semimetal dissolved by concentrated than by dilute nitrous acid, 489. Effects of the marine acid on zinc, 490. Vitriolic acid can scarce dissolve bismuth, 491. Nitrous acid dissolves it readily, 492. Marine acid scarce acts upon it, 493. Effects of vitriolic acid on nickel, 2d 493. Of nitrous acid, 494. Of marine acid, 495. Of the vitriolic acid on cobalt, 496. Of nitrous acid, 497. Of the marine acid, 498. Of vitriolic acid on regulus of antimony, 499. Of nitrous acid, 500. Of the marine acid, 501. Of vitriolic acid on regulus of arsenic, 502. Of nitrous acid, 503. Of marine acid, 504. Quantity of phlogiston contained in it, 509. Why the marine acid acts so weakly, 510. How to distil acid spirits, 575. Luting proper for them, 577. Of the vitriolic acid and its combinations, 612, *et seq.* See *Vitriolic*. Mistake of Mr Morveau concerning the excess of acid contained in alum detected by Mr Kirwan, 642. This excess necessary to render alum soluble in water, 643. Too great an excess prevents the crystallization of the salt, 681. This excess best remedied by the addition of pure clay to the liquor, 682, *et seq.* The superfluous acid might be advantageously distilled, 689. Nitrous acid and its combinations, 722, *et seq.* See *Nitrous*. Experiment on the transmutation of vitriolic into nitrous acid, 721. Inconclusive, 722. Marine acid and its combinations, 782, *et seq.* This acid may be dephlogisticated by spirit of nitre or manganese, 790. Mr Scheele's method of doing it by means of manganese, 791. Properties of dephlogisticated marine acid, 792. A mistake of Stahl concerning its conversion into nitrous acid accounted for, 793. See *Marine*. Fluor acid discovered by Mr Margraaf, &c. 826, *et seq.* Marine acid proved to be different from that of fluor, 835. And likewise the vitriolic, 836. See *Fluor*. Of the acid of borax and its combinations, 858—866. See *Borax* and *Sal Seducativus*. Of the acetous acid and its

its combinations, 867—884. See *Acetous*. Of the acid of tartar, 885—895. See *Tartar*. Of the acid of sugar, 896—903. See *Sugar* and *Saccharine*. Of the phosphoric acid, 904—907. See *Phosphoric*. Of the acid of ants, 2d 907, 908. See *Ants*. Of the acid of amber, 909—915. Purified by marine acid, 911. Effects of spirit of nitre on it, 912. Of oil of vitriol, 913. Of the acid of arsenic, 916, *et seq.* Nitrous acid decomposes arsenic, 918. As does also dephlogisticated marine acid, 919. See *Arsenic*. Of the acid of molybdæna, 958, *et seq.* Effects of the arsenical acid on molybdæna, 959. Nitrous acid acts violently upon it, 960. See *Molybdæna*. Of the acid of lapis ponderosus, tungsten or wolfram, 967, *et seq.* See *Tungsten*. Difference between the acids of molybdæna and tungsten, 971. Why Bergman supposed both these to be metallic earths, 972, 973. Of the acid of milk, 974, *et seq.* Contains the acids of tartar and sea-salt, 975. Of the acid of sugar of milk, 980, 981. See *Milk*. Of the acid of human calculus, 982. See *Calculus*. Of the acid of benzoïn, 984, *et seq.* See *Flowers* and *Benzoïn*. Whether the acid of sugar or of tartar is the basis of the anomalous vegetable acids, 996. Dr Crell's method of crystallizing the acid of lemons, 997. The crystallized salt cannot be converted into acid of sugar, 999. Product of the acid of tartar by dry distillation, 1000. Acetous acid almost entirely destructible by fire, 1001. Of the transmutation of the vegetable acids into the acetous acid, 1002—1015. See *Acetous*. Phenomena resulting from the mixture of acid spirits with one another, 1040. Solution of salts promoted by vitriolic acid, 1048. Terra ponderosa usually found in a state of combination with this acid, 1049. Effects of marine acid on aerated terra ponderosa, 1053. See *Terra Ponderosa*. White matter contained in the vitriolic acid shown to be gypsum, 1059. Vitriolic acid easily discoverable by solution of terra ponderosa, 1058. Marmor metallicum soluble in very concentrated vitriolic acid, 1063. Why the fluor acid will not dissolve flint directly, 1073. Why the siliceous earth sometimes cannot be precipitated by an acid without the assistance of heat, 1079. Earth of flints precipitated by fluor acid, 1080. Neither the nitrous nor marine acid necessary for the preparation of aurum fulminans, 1117. Vitriolic acid partially dissolves arsenic, 1271. Marine acid dissolves it totally, 1272. Phlogisticated alkali precipitates arsenic from its solution in marine acid, and from that only, 1273. Arsenic decomposed by dephlogisticated marine acid, 1274. Phenomena of arsenic with nitrous acid, 1280. Butter of arsenic can scarce be made to unite with marine acid, 1282. Regulus of arsenic converted by the vitriolic acid into white

No 76.

arsenic, 1292. Phenomena of cobalt with vitriolic acid, 1300. With nitrous acid, 1301. With marine acid, 1302. With the acid of borax, 1303. Effects of the nitrous acid on nickel, 1313. Dephlogisticated marine acid the only solvent of platina, 1319. Solution of that metal in an aqua regia composed of nitrous acid and spirit of salt, 1323. In one composed of marine acid and nitre, 1324. Solution of calx of platina in marine acid lets fall a crystalline powder on the addition of vegetable alkali, 1325. But not that in the nitrous acid, 1326. Phenomena of manganese with vitriolic acid, 1360. Phlogisticated vitriolic acid entirely dissolves it, 1361. And likewise the phlogisticated nitrous acid, 1363. Effects of it on marine acid, 1364. Entirely dissolved by this acid without addition, 1365. Fluor acid can scarcely dissolve it, 1366. Or phosphoric acid, 1367. Acid of tartar partly dissolves manganese, 1368. Acetous acid effects a solution with difficulty, 1369. Acid of lemons entirely dissolves it, 1370. As does also water impregnated with aerial acid, 1371. No pure acid can dissolve manganese after it has lost its phlogiston, 1375. Why the concentrated vitriolic acid dissolves it without addition, 1378. Why the volatile fully hureous acid dissolves it, 1379. Effects of the nitrous acid on it explained, 1380. Existence of phlogiston proved in the marine acid, 1381. Explanation of the effects of acid of tartar and of lemons, 1382. And of fluor acid, 1383. Effects of digesting manganese and volatile alkali with nitrous acid, 1393. An acid supposed to occasion the taste of essential oils, 1420. A new one discovered by Mr Homberg, 2d 825. See *Acids*. See also *Vitriolic*, *Nitrous*, *Marine*, *Acetous*, *Tartar*, *Fluor*, &c.

Acids, one of the principal classes of salts, 169. Divided into mineral, vegetable, and animal, *ib.* Their different action compared with that of alkalis, 171. Unite with alkalis into neutral salts, sometimes with, and sometimes without, effervescence, 172. Change the blue colour of vegetables to red, 173. Different degrees of their attraction to alkalis, 174. The vitriolic strongest in a liquid state, *ib.* Marine acid strongest in a state of vapour, *ib.* The fixed acids strongest when the subjects are urged with a violent heat, *ib.* Attraction of the different acids for phlogiston, 175. The acids are capable of forming an union with metals or earths, 176. Will leave a metal to unite with an earth, 176, 177. And an earth to unite with a mild volatile alkali, *ib.* Will leave a volatile, to unite with a fixed alkali, *ib.* Some will leave a fixed alkali to unite with phlogiston, 175, 178. Exceptions to these rules, 179. Why precipitates are sometimes thrown down by them, 221. Explanation of the

decompositions effected by acids alone, 266. Quantities of the different acids taken up by various bases, 268. This quantity expressive of the quantity of attraction they have for each of these bases, 269. Vitriolic salts decomposed by the nitrous and marine acids, 275. Acids unite with alkalis by giving out fire, and quit them by receiving it, 286. The attractive powers of acids to metals difficult to be determined, 296. Proportions of the different metallic substances taken up by the different acids, 298. Metals have a greater affinity with acids than alkalis, 299, 303. Explanation of the table of the affinities to the different metallic substances, 316. An equal quantity of all the mineral acids taken up by vegetable fixed alkali, 402. Quantity of this alkali requisite to saturate the several acids, 403. Acids can never totally dephlogisticate metallic earths, 407. Concentrated acids phlogisticated by alkalis, 409. Of the time required by mixtures of the mineral acids with water to attain their utmost density, 422. Of the alterations of their densities by various degrees of heat, 423. Acids cannot dissolve calcined magnesia without heat, 442. Phenomena of different acids with inflammable substances, 518. Metals soluble in acids, 520. Calcination and increase of their weight by acids, 523. How to distil the mineral acids, 575. Vitriolic, phosphoric, and acetous, acids, found in the resin extracted from the residuum of vitriolic ether, 2d 722. Nitrous, marine, and phosphoric acids, capable of expelling the fluor acid, 2d 850. Acids of sal ammoniac and nitre expelled by salt of amber, 910. Of the anomalous vegetable acids, and the resemblance which vegetable acids in general bear to one another, 984, *et seq.* How the anomalous vegetable acids are divided, 993. Of the essential acids, 994. Empyreumatic acids, 995. Whether the acid of sugar or of tartar be the basis of the vegetable acids, 996. Dr Crell's proofs that all the vegetable acids may be reduced to one, which is contained in the purest spirit of wine, 1006. Phenomena attending the dissolution of vitriolic salts in nitrous or marine acid, 1041. Nitrous or marine acids are not necessary for the preparation of aurum fulminans, 1117. Copper undergoes a change by combination with vegetable acids, 1151. Colouring matter of Prussian blue expelled by acids, and then taken up by the atmosphere, 1177. Phenomena of arsenic with different acids, 1275. Manganese becomes insoluble in pure acids, by losing its phlogiston, 1375. See *Acids*, *Vitriolic*, *Marine*, *Vegetable*, &c.

Acids and Alkalis: inaccuracy of the common tests for trying them, 1549. Mr Watt's experiments on this subject, *ib.* His method of preparing a test from cabbage and

other plants, 1550, *et seq.* Absorb air during their formation, 1543.

Adopters, or *Aludels*, described, 579.

Aerated terra ponderosa, analyzed by Dr Withering, 1057.

Aerial acid: the conversion of dephlogisticated air into it by means of charcoal, a proof of the identity of phlogiston and charcoal, 151. Description of the terra ponderosa combined with the aerial acid, 1051. Aerial acid and phlogiston supposed to exist in the colouring matter of Prussian blue, 1196. See *Fixed Air*.

Affinities, quiescent and divellent, described, 267. Table of the affinities of the three mineral acids to the different metals, 298. Explanation of this table, 316. Table of the proportional affinities of the metallic calces to phlogiston, 330. Dr Black's general table of affinities, 553.

Affinity of the different metals to phlogiston, how determined, 318.

Agents in chemistry, how distinguished from the objects of it, 22.

Air supplies inflammable bodies with the heat they emit during combustion, 157. Too great a quantity of air will diminish the heat of a fire, or even put it out entirely, and why, 159. Only a small quantity of air can be obtained from metals when calcined, 191. Different kinds of it produced during the dissolution of metals, 201. Specific gravity of the different kinds of air according to Fontana, 375. Exposure of aluminous ores to the air sometimes has the same effect with roasting them, 663. Vitriol deprived of its phlogiston by exposure to the air, 687. Lixivium sanguinis loses its colouring matter by exposure to the air, 1172. This colouring matter taken up by the air after it has been expelled by acids, 1177. Absorbed during the formation of acids, 1543.

Air-bubbles produced in water during the act of congelation, occasion its expansion and prodigious force, 109. They are extricated by a part of the latent heat discharged from the water at that time, 110.

Alchemists: their labours were of some advantage to chemistry, 13.

Alchemy first mentioned by Julius Firmicus Maternus, a writer of the 4th century, 8. Supposed to be first derived from the Arabians, 10. The pretenders to it very numerous in the beginning of the 16th century, 12.

Alchorne's experiments on the effects of mixing tin with gold, 1092, *et seq.*

Alembic, derivation of that word, 5.

Alembroth sal, made by subliming equal quantities of corrosive sublimate and sal ammoniac, 1047. Said to dissolve all the metals, *ib.* Convertible by repeated distillations into a fluid that cannot be raised into vapours by the strongest heat, *ib.*

Algaroth powder, prepared by precipitating butter of antimony with water, 821. The most proper material

terial for the preparation of emetic tartar, 1259. Shown by Mr Scheele to be a regulus half calcined by dephlogisticated marine acid, 1261. His receipt for preparing it cheap, 1262.

Alkali less attracted by nitrous acid than silver, 301. Metallic earths more strongly attracted by acids than volatile alkali, 303. Why the metallic earths seldom decompose those salts that have an alkali for their basis, 304. Quantity of alkali, acid, and water, contained in digestive salt, 379. Mr Kirwan's method of saturating an alkali exactly with an acid, 381. Quantity of mild and caustic vegetable fixed alkali saturated by a given weight of marine acid, 382. Quantity of alkali, water, and acid, in nitre, 391. Of the same ingredients in vitriolated tartar, 398. Vegetable fixed alkali takes up an equal quantity of all the mineral acids, 402. Specific gravity of the vegetable alkali determined, 412. Quantity of earth contained in this alkali, 413. Of the quantity of fixed air contained in oil of tartar and dry vegetable alkali, 414. Quantities of fixed air contained in impure vegetable alkali determined by Mr Cavendish, 417. Exact quantity of acid taken up by mild fixed alkali, 418. Mineral alkali how prepared by Mr Kirwan for his experiments, 419. Of the quantity of vitriolic acid necessary to saturate 100 grains of it, 430. Quantity of dephlogisticated nitrous acid taken up by it, 432. Of the marine acid, 433. Proportion of pure alkali, water, and fixed air, in crystallized mineral alkali, 434. Excess of acid in aluminous liquor cannot be removed by mineral alkali, though it may be by the vegetable and volatile kinds, 680. Vitriolic acid combined with fixed alkali, 628, 629. With volatile alkali, 633. Nitrous acid combined with vegetable fixed alkali, 740. With fossil alkali, 741. With volatile alkali, 745. Marine acid combined with vegetable alkali, 794. With mineral alkali, *ib.* With volatile alkali, 795. Fluor acid combined with fixed alkali, 850. With volatile alkali, 851. Glass corroded by the salt formed from the union of fluor acid and volatile alkali, 854. Sedative salt combined with the vegetable alkali, 862. With the mineral alkali, 863. Acetous acid combined with vegetable alkali, 868. With mineral alkali, 869. With volatile alkali, 870. Acid of tartar combined with vegetable alkali, 889. With fossil alkali, 891. With volatile alkali, 892. Acid of sugar with vegetable alkali, 899. With fossil alkali, *ib.* Incredible quantity of volatile alkali saturated by it, 900. Phosphoric acid with fixed alkali, 906. With volatile alkali, 904. Acid of ants combined with fixed and volatile alkali, 908. Acid of amber with fixed alkali, 909.

VOL. IV. Part II.

With volatile alkali, *ib.* Acid of arsenic with vegetable fixed alkali, 925. With mineral alkali, 927. With volatile alkali, 928. Vegetable alkali capable of being reduced into crystals by means of spirit of wine, 1017. Without any addition into deliquescent crystals, *ib.* Mineral alkali always assumes a crystalline form, *ib.* Change on the vegetable alkali by being united with spirit of salt, 1018. Difference betwixt the vegetable and mineral alkali, 1019. The former has a greater attraction for acids, *ib.* Both of them composed of a caustic salt and fixed air, 1020. Of the volatile alkali, 1030. Of the method of distilling it, 1031. Of its rectification, 1032. Combined with fixed air, 1033. Combined with metals, 1034. With inflammable substances, 1055. With expressed oils, *ib.* With essential oils and spirit of wine, 1036, 1037. With sulphur, 1038. Solutions of calcareous earth decomposed by mild volatile alkali, 1046. Caustic fixed alkali throws down an insoluble precipitate from solution of terra ponderosa, 1056. Vegetable alkali precipitates marmor metallicum unchanged from concentrated vitriolic acid, 1064. Volatile alkali precipitates siliceous earth more completely than any other, 1074. A triple salt formed by precipitating this earth with fixed alkali, 1075. Siliceous earth dissolved by boiling in solution of alkali, 1076. A remarkable attraction betwixt fixed alkali and siliceous earth in the dry way, 1077. The use of volatile alkali only lately known in the preparation of aurum fulminans, 106. This alkali the cause of the explosion, 1121. It exhibits a flash when thrown into a crucible by itself, 1122. Used in the preparation of fulminating silver, 1139. Phlogisticated alkali loses its peculiar properties, 1168. Colouring matter of Prussian blue unites with volatile alkali, 1182. Forms a kind of ammoniacal salt with it, 1186. Volatile alkali produced by distilling Prussian blue, 1197. Phenomena on distilling metallic precipitates thrown down by Prussian alkali, 1198. Volatile alkali capable of uniting with fixed alkali and phlogiston so as to be capable of sustaining a great degree of heat, 1202. Phlogisticated alkali cannot precipitate arsenic except from marine acid, 1273. Effects of volatile alkali on nickel, 1314. Mineral alkali capable of decomposing crystals of platina, but not the vegetable alkali, 1322. Crystalline powder precipitated from solution of calx of platina in marine acid, by means of vegetable alkali, 1325. But not from the solution in nitrous acid, 1326. Whether mineral alkali can decompose solutions of platina, 1328. Fifty-six times as much of it required for this purpose as of vegetable alkali, 1329. Effects of the volatile alkali

on solutions of platina, 1330. Volatile alkali destroyed by manganese attracting its phlogiston, 1394. See *Alkalies*. Wiegand's account of the phenomena attending the dissolution of copper in it, 1035. Its effects on dephlogisticated spirit of salt, 1485. Higgins first discovered its constituent parts, 1553. Procured it from nitrous acid and tin, *ib.* Effect of the electric spark on a mixture of it and dephlogisticated air, 1555. True composition of it, 1556.

Alkalies; one of the general classes of salts, 169. Divided into fixed and volatile, 170. The former subdivided into vegetable and mineral, *ib.* Difference between their action and that of acids, 171. Neutral salts form them by being united with acids, 172. Vegetable blues changed green by them, 173. Different degrees of attraction betwixt them and acids, 174. Phenomena attending the precipitation of metals by them, 220. Volatile alkalies particularly apt to form triple salts, 274. Why they precipitate the metals, 300. Metals have a greater affinity with acids than alkalies, though the latter separate them from acids, 299. Why luna cornua cannot be reduced without loss by alkaline salts, 314. Alkalies phlogisticate concentrated acids, 409. Proportions of the different ingredients in volatile alkalies, 436. Stone-ware vessels corroded by caustic fixed alkalies, 595, 596. Advantages of using clay rather than alkalies for absorbing the superfluous acid in aluminous liquor, 683. Solution of silver decomposed with difficulty by alkalies, 756. How the alkalies are procured, 1016. Differences between the vegetable and mineral alkalies, 1019. Combinations of them with sulphur, 1021. With expressed oils, 1026. With essential oils, 1027. With phlogiston, 1028. Differences between the fixed alkalies obtained from different vegetables, *ib.* Solution of terra ponderosa in marine acid precipitated by all the alkalies, whether mild or caustic, 1054. Alkalies dissolve lead by boiling, 1216. Effects of arsenic on alkalies, 1290. Test for them and acids, 1549. See *Alkali, Acid, and Acids, Alkaline salts*. See *Alkali and Alkalies*. Alkaline ley improper for extracting the flowers of benzoin, 989.

Alfen-Moor in Cumberland, a kind of aerated terra ponderosa found near that place, 1051.

Aludels, or *Adopters*, described, 579.

Alum: cannot form Glauber's salt by being dissolved in water along with common salt, 272. Mistake of Dr Croll on this subject corrected, *ib.* Nor blue vitriol by boiling it with copper filings, 349. Why its precipitate retains part of the acid, 408. Its earth contains 26 per cent. of fixed air, 446. Proportions of the ingredients in it, 447. The salt always contains an

excess of acid, 448. Proportion of the earth of alum taken up by nitrous acid, 449. By marine acid, 450. Alum of the ancients different from ours, 637. The name of *Roeb-alum* derived from *Rocco*, a city of Syria, 638. First made in Europe in the middle of the 15th century, in Italy, 639. Made in Spain in the 16th century, 640. In England and Sweden in the 17th, *ib.* Its component parts first discovered by Boulduc and Geoffroy, 641. Found to contain an excess of acid, *ib.* This denied by Mr Morveau, 642. His mistake discovered by Mr Kirwan, *ib.* Insoluble in water when deprived of its superfluous acid, 643. Easily calcinable in the fire; after which it is called *burnt alum*, *ib.* Bergman's method of finding the proportion of the ingredients it contains, 644. Difficulty of obtaining the earth of alum in a pure state, 645. Mr Bergman's account of the proportion of the ingredients, 646. Whether earth of alum be a pure clay or not, 647. Dr Lewis's experiment, tending to show that clay undergoes some change by being converted into earth of alum, 649. Quantities of alum soluble in warm and in cold water, 650. Bergman's account of the Swedish ores of alum, 651. Component parts of the aluminous schist, 652. How changed by roasting, 653. Presence of pyrites the only requisite for the production of alum, 654. Ores containing alum ready formed only to be met with in volcanic countries, 655. Ores of alum at Solfatara in Italy, 656. Analysed by Mr Bergman, 657. Hessian, Bohemian, and Scanian, ores, 658. Alum, sulphur, and vitriol, extracted from the same ore, 659. Alum slate found at York in England, 660. Bergman's directions for the preparation of alum, 661. Uses of roasting the ore, 662. Exposure to the air sometimes has the same effect with roasting, 663. Earthy ores unfit for either purpose, 664. Method of roasting the ore in Sweden, 665. How often the operation is to be repeated, 666. Danger of increasing the heat too much, 667. Rinman's method of roasting the ore at Garphyttan, 668. Method of burning the hard ores at Tolfa in Italy, 669. Method of elixating the burned ore at Garphyttan, 670. Heat and cold water used for this purpose in different places, *ib.* Different methods of elixation, 671. Singular circumstance by which the alum is said to be destroyed, 672. Of the proper strength of the lixivium before it is committed to evaporation, 673. Construction of the evaporating vessel, 674. How far the liquor ought to be evaporated, 675. Of the first crystallization, 676. Depuration of the crystals, 677. Bergman's remarks on the proper form of the coolers, 678. They ought to be of a conical shape, *ib.* Aluminous ley contains

so much acid that it cannot be crystallized without abstracting part of the excess, 679. Which may be done by the addition of vegetable fixed alkali, or volatile alkali, but not by the mineral alkali, 680. Experiments in proof of the excess of acid preventing the crystallization of alum, 681. Another, showing the utility of adding clay to the aluminous ley, 682. Advantage of using it in preference to the alkalies, 683. Alum generally contaminated by dephlogisticated vitriol, 684. This defect remedied by the addition of pure clay, 685. Perfect vitriol cannot be destroyed by clay, 686. How the phlogiston of vitriol may be dissipated, 687. Epsom salt supposed to be producible from the mother liquor of alum, 688. Superfluous acid of this liquor might be advantageously distilled, 689. Combination of arsenical acid with earth of alum, 938. How to make it shoot into cubical crystals, 689.

Alum slate. See *Alum*.

Alum works, when first set up in Italy, 639. In Spain, England, and Sweden, 640.

Aluminous ores. See *Alum*.

Amalgamation of silver: a difficulty concerning it solved by Mr Bergman, 217. Of copper with mercury, 1152. Dr Lewis's methods, 1153. Amalgamation of mercury with different metals, 1232.

Amber, acid of, 908. Mr Pott's experiments on it, 909. Requires a large quantity of water for its solution, ib. Rendered somewhat purer by crystallization, ib. Partly destroyed by sublimation, ib. Forms a neutral saline liquor with fixed alkalies which does not crystallize, ib. Forms an oily fluid with volatile alkali, ib. Extricates the acids of sal ammoniac and nitre, 910. Purified by marine acid, 911. Does not contain any mineral acid, ib. Converted almost entirely into a liquid by distillation with spirit of nitre, 912. Most of it rises in a solid form by distilling with oil of vitriol, 913. Forms a solution of quicklime, mostly resembling the same, in vegetable acids, 914. Its effects on the metals, 915. Amber, by distillation, yields an acid salt and oil, 1444. Difference in the product by certain additions sometimes used in the distillation, ib. Addition of sea-salt produces the greatest yield of salt of amber, ib. Greatest quantities of amber distilled in Prussia, 1445. Distilled there without any addition, ib. The salt purified by being kept on bibulous paper to absorb the oil, ib. Crystals resembling it formed by the union of marine acid with phlogistic matters, 1481. Methods of purifying its salt, 1494. An acid of another kind passes over in distilling this substance, 1493. Combination of the salt with alkalies, earths, and metals, ib. Mr Keir's remarks on the nature of salt of amber, 1495.

Ambergrease yields a product on distillation similar to that of amber, 1446.

America: method of making nitre there, 726.

Ammoniac, vitriolic, decomposed by solution of silver, 306. How to prepare this kind of sal ammoniac, 633. Erroneously said to have powerful effects on the dissolution of metals, ib. Mr Pott's experiments on it, ib. Nitrous ammoniac, how prepared, 745. Is soluble in spirit of wine, ib. Deflagrates without any addition, ib. The principal ingredient in Ward's white drop, 746. Common sal ammoniac prepared from marine acid and volatile alkali, 795. Dissolves resins according to Mr Gellert, ib. Its volatility diminished by repeated sublimations, ib. A small quantity producible by distilling sea-salt with charcoal, &c. ib. Originally prepared in Egypt, 796. A method of making it described, ib. Vegetable ammoniac formed of the acetous acid and volatile alkali, 870. Can scarce be procured in a dry state, ib. Acid of common sal ammoniac extricated by acid of amber, 910. And by the arsenical acid, 932. Volatile sal ammoniac, how prepared, 1033. Common sal ammoniac not decomposed by regulus of cobalt, 1304. Effects of it on nickel, 1312. Solution of it precipitates a solution of platina, 1352. The precipitate fusible by a strong forge heat, 1353. This fusion supposed by Macquer not to be perfect, 1354. Effects of manganese on it, 1392.

Ammoniacal salt, formed by the union of the colouring matter of Prussian alkali with volatile alkali, 1186.

Animal earth, very insoluble in acids, and infusible in the fire, 515. Earth of the soft parts more soluble than that of the hard, ib. This earth erroneously supposed to contain phosphoric acid, ib. Animal fats analysed, 1428. Yield a great quantity of oil by distillation, ib. A particular kind of acid produced from tallow, 1429. How to rectify the empyreumatic oil of animals, 1427. Of animal and vegetable substances, 1451.

Anomalous earths, 513. Anomalous vegetable acids, how divided, 993.

Antimony: why nitrous acid precipitates a solution of it, 200. Precipitates of it by common and phlogisticated alkalies, 246. Of its precipitates with other metals, 365. A triple salt formed by regulus of antimony, marine acid, and iron, 366. Another with the regulus, marine acid, and copper, 367. Of the solution of the regulus in vitriolic acid, 499. Of its combination with that acid, 709. Corroded by the nitrous acid, 768. Regulus of antimony combined with marine acid, 821. Of the amalgamation of it with mercury, 1237. Renders bismuth capable of uniting with cobalt, 1251. The regulus particularly treated of, 1252,

et seq. Has the appearance of a star on its surface when well made, 1252. Sublimable into flowers, 1253. Different methods of preparing the regulus, 1254. Considerable differences in the regulus, according to the different substances used to absorb the sulphur, 1255. Of the regulus made with cawk, 1256. This semimetal easily miscible with mercury, 1255. Enters into the composition of speculums and printing types, 1256. Was the basis of many medicinal preparations, now disused on account of their uncertain operation, ib. Glass of antimony, how prepared, 1257. More violent in its effects than the regulus itself, ib. Preparation of emetic tartar from glass of antimony and pulvis algaroth, 1258, *et seq.* See *Tartar* and *Algaroth*. Preparation of golden sulphur of antimony and kermes mineral, 1263. Diaphoretic antimony, 1264. Crocus metallorum, 1265. Butter of, Mr Dolfus's method of preparing it, 821.

Antiphlogisticians: their absurd way of explaining the explosion of fulminating silver, 1144.

Ants yield an acid by distillation or infusion in water, 2d 907. Its nature and properties, 908.

Ants, acid of, composes an ammoniacal liquor with volatile alkali which cannot be reduced to a dry salt, 908. Crystallizes with fixed alkalies, ib. And with coral chalk or quicklime, ib. Dissolves calcined copper, and forms beautiful crystals with it, ib. Makes a peculiar kind of saccharum saturni with minium, ib. Its effects on other metals, ib. Different methods of procuring their acid, 1502. Properties of the pure acid, 1503. Has an affinity with the acetous, 1504. Its effects on metals, 1505.

Apples, their acid treated of, 1506. Its properties, 1509, 1511. How procured in perfect purity, 1510. Produced from sugar by means of nitrous acid, 1512. Mr Keir's opinion concerning its nature, 1514.

Aqua fortis, procured by means of arsenic of a blue colour, 739.

Aqua-regia, best kind of it for dissolving gold, 481. Quantity of gold taken up by it, 482. How prepared from nitrous acid and common salt, 788. Of the solution of gold in aqua-regia, 1099. Solution of platina in an aqua-regia composed of nitrous and marine acids, 1323. In one made with marine acid and nitre, 1324. Various methods of preparing it, 1488. Differences between the liquors prepared by these methods, 1489. How to deprive it of its volatility, 1548.

Aquila alba, a name for *mercurius dulcis*, 814.

Arabians, the first broachers of alchemy, 10.

Arbor Diana, how made, 754.

Ardent spirits, dissolve camphor in great quantity, 1425.

Argand's lamps, used for lamp-furnaces 611. Doubtful whether they be preferable for this purpose to Lewis's or not, ib.

Argentine flowers, formed of regulus of antimony, 1253.

Argillaceous earth, in what it differs from the calcareous, 312. Tobacco-pipe clay the purest earth of this kind, ib. Absorb colours, ib. Resist the utmost violence of fire by themselves, but melt by a mixture with chalk, ib. Combination of the argillaceous earth with vitriolic acid, 637, &c. See *Alum*.

Argonauts, origin of the fable of them, 9.

Arsenic: Of its dissolution and precipitation 243, 368. Calculation of the quantity of phlogiston contained in regulus of arsenic, 318. Precipitated by bismuth from the nitrous acid, 369. And by copper from the marine, 370. Quantity of vitriolic acid taken up by regulus of arsenic, 502. Of nitrous acid, 503. Of marine acid, 504. Compounded of a particular kind of acid and phlogiston, 548. Unites with sulphur, ib. Is soluble in water, ib. Expels the acid of nitre, ib. Reason of this decomposition, ib. Phenomena on distillation with the vitriolic acid, 711. Dephlogisticated by the nitrous acid, 770. Of the adulteration of corrosive sublimate by arsenic, 818. Oil and butter of arsenic, 823. Formed by subliming arsenic with corrosive sublimate, ib. Of the arsenical acid, 916, *et seq.* See *Arsenic*, acid of. A single grain of regulus of arsenic destroys the malleability of an ounce of gold, 1095. Has a great affinity with tin, 1219. Methods of separating arsenic from tin, 1220. The crackling noise of tin in bending supposed to arise from arsenic, 1221. Arsenic found in some places of Germany in a metallic form, 1266. The regulus easily convertible into common white arsenic by dissipating part of its phlogiston, 1267. Why the arsenical calx may be mixed with other metals which will unite with it in its reguline state, 1268. Of the solution of the calx in water, 1269. In spirit of wine, 1270. Forms a very insoluble and fixed salt with vitriolic acid, 1271. Dissolves in large quantity in the marine acid, and forms a more volatile salt with it, though difficultly soluble in water, 1272. Resemblance of this solution to butter of arsenic, ib. Phlogisticated alkali precipitates arsenic from marine acid, and from that only, 1273. Arsenic decomposed by dephlogisticated marine acid, 1274. Phenomena exhibited by it with other acids, 1275. Liver of arsenic formed by combining it with fixed alkali, 1276. Arsenic unites with some metals, and crystallizes with iron and zinc, 1277. Unites readily with sulphur, 1278. Compounds thence resulting, ib. 1279. Phenomena exhibited by mineralized arsenic with nitre, 1280. Butter

Butter of arsenic, 1281. This substance can scarce be made to unite with marine acid, 1282. Of the oil of arsenic, 1283. Of the mineralization of arsenic by sulphur, 1284. How to prepare pure regulus of arsenic, 1285. A native regulus called *mispickel*, 1286. This contains a large quantity of iron, which will not obey the magnet till the regulus is dissipated, ib. Great volatility of the reguline arsenic, 1287. It destroys the malleability of the metals with which it unites, 1288. May be expelled by heat from all of them except platina, 1289. Volatilizes all of them except platina, ib. Effects of arsenic upon alkaline salts and nitre, 1290. Decomposes corrosive sublimate, 1291. The regulus converted into white arsenic by vitriolic acid, 1292. Effects of it on metallic solutions, 1293. Platina may be melted by means of arsenic, 1349. Effects of it on manganese in conjunction with nitre, 1391. Phenomena on distillation with manganese, 1395.

Arsenic, acid of, first discovered by Mr Scheele, 916. Two methods of procuring it, 917. By means of nitrous acid, 918. By dephlogisticated spirit of salt, 919. This acid equally poisonous with the white calx, 920. Easily resumes its phlogiston, 921. Takes fire and sublimes instantaneously into regulus with charcoal, 922. Becomes black and thick with oil of turpentine, 923. With sulphur, 924. Crystallizes into a neutral salt with vegetable alkali, 925. This salt decomposed and forms a regulus with charcoal, 926. Forms a crystallizable salt when perfectly saturated with mineral alkali, but requires an excess of acid to make it crystallize with the vegetable alkali, 927. Forms likewise a crystallizable salt with the volatile alkali, 928. Expels the vitriolic acid from vitriolated tartar and Glauber's salt, 929. And likewise those of nitre and common salt, 930, 931. Phenomena on distilling it with sal-ammoniac, 932. Decomposes spathum ponderosum and gypsum: but cannot expel the fluor acid, 339, 934. Precipitates lime-water, 935. Forms a crystalline salt with chalk, 936. But refuses to crystallize with magnesia, 937. Or with earth of alum, 938. Does not dissolve white clay, 939. Dissolves terra ponderosa, 940. Has no effect on gold or platina, 941, 942. Dissolves silver in the dry way by a violent heat, 943. Fixes quicksilver, 944. Produces corrosive sublimate by distillation with mercurius dulcis, 945. No butter of arsenic obtained by this process, 946. Dissolves copper, 947. Forms a very thick gelatinous solution of iron, 948. Dissolves lead in the dry way, 949. And likewise tin, 950. Dissolves zinc with effervescence, 941. But cannot dissolve bismuth, 952. Nor regulus of antimony, 953. Dissolves cobalt par-

tially, 954. But not nickel, 955. Dissolves a small quantity of manganese, 956. Converts regulus of arsenic into the white arsenical calx, 957. Strange phenomena from it and the acetous acid, 2d 957, 1521. M. Pelletier's method of procuring the acid of arsenic, 1496. Differences concerning the weight of the acid so procured, ib.

Asbes of different vegetables, Dr Gmelin's account of their colours, &c. 1089.

Attraction: Fire detained in bodies partly by it and partly by the pressure of the surrounding fluid, 55. Of chemical attraction, 162. This kind of attraction not equally strong between all bodies, ib. Different degrees of it betwixt the different acids and alkalies, 174. Attraction of phlogiston supposed to be the cause of causticity, 219. Kirwan's definition of chemical attraction, 260. Difference betwixt it and cohesion, 261. Geoffroy's rule for determining the degrees of chemical attraction, 262. True method of ascertaining the quantity of attraction each of the acids has for the different bases, 265. This quantity expressed by that of the bases taken up by the different acids, 269. Attraction of metallic calces to phlogiston determined, 326.

Attractive powers of different substances best expressed by numbers, 264. Difficulties in determining the attractive powers of the different acids to metallic substances, 296.

Aurum fulminans, its nature and properties, 1103. Was known in the 15th century, 1104. The first directions for its preparation given by Basil Valentine, 1105. The use of volatile alkali for this purpose but lately known, 1106. Different accounts of the increase of weight in the metal by being converted into aurum fulminans, 1107. Explodes with incredible force, 1108. Twenty grains of it more than equivalent to half a pound of gun-powder, ib. Does not explode in close vessels, 1109. The utmost caution necessary in managing it in the open air, ib. Dr Lewis's account of the heat necessary to make it explode, 1110. Explodes by friction scarce sufficient to occasion any heat, 1111. Terrible accidents occasioned by it, 1112. The force of the explosion directed equally every way, 1113. Particulars relating to the explosion, ib. Will not explode when moist, 1114. Quantity of elastic vapour produced during the explosion, ib. Cause of the explosion attributed to a saline principle, 1115. This opinion shown to be erroneous by Mr Bergman, 1116. Why the fulminating property is destroyed by trituration with fixed alkali, ib. The explosion rendered more violent by boiling with fixed alkali, ib. Why the fulminating property is destroyed by boiling with too strong a solution of alkali, or with

concentrated vitriolic acid, ib. Neither the presence of nitrous or marine acids necessary for the production of fulminating gold, 1117. The explosion is not occasioned by fixed air, 1118. How the fulminating calx may be prepared, 1119. The calx most readily thrown down by volatile alkali, ib. A fulminating calx produced from solution of gold in dephlogisticated spirit of salt, ib. Mr Bergman's theory of the cause of the explosion, 1120. Volatile alkali the true cause of it, 1121. Great quantity of elastic fluid generated by the explosion of aurum fulminans, 1123. Why a slight calcination destroys the fulminating property, 1124. Why the calx will not explode in close vessels, 1125.

Aurum Mosaicum, or *Musivum*, how prepared, 1224.

BACON (Lord), his opinion of heat, 28, 29. See *Verulam*.

Baldwin's phosphorus prepared from solution of calcareous earth in spirit of nitre, 749.

Balneum arenae, or *sand-bath*, described, 578.

Balsams of sulphur, how prepared, 1401. Vegetable balsams whence procured, 1432. May be considered as essential oils thickened by the dissipation of some of their more volatile parts, ib. Analysis of them exemplified in turpentine, 1437.

Barofelenite, a name for the marmor metallicum, or combination of terra ponderosa with vitriolic acid, 1050.

Basil Valentine, the first who gave directions for the preparation of aurum fulminans, 1105.

Beaume's observations on gypsum, 636. His account of the formation of sedative salt ill founded, 862. Vitrifies a calx of platina, 1352.

Beccaria's observations on phosphori, 1085.

Bell-metal, composed of copper and tin, 1155. Its specific gravity greater than that of either of the metals singly, 1156.

Bellorus, when to be used in chemical operations, 608.

Bells: Reaumur's hint concerning an improvement in their shape, 1211.

Benzoin, yields a fragrant acid salt by sublimation, 984. The same obtained by lixiviation, 985. Quantity obtained by both these methods, 986. Mr Scheele's experiments in order to procure all the flowers benzoin is capable of yielding, 987, &c. Boiling with chalk insufficient, 988. Or with alkaline ley, 989. Boiling with lime the best method, 990. Scheele's receipt for preparing the flowers of benzoin by this method, 991. The flavour of these flowers destroyed and reproduced at pleasure, 992. The gum analyzed, 1439. Acid of, investigated by Mr Lichtenstein, 1530. Effects of nitrous acid upon it, 1531. Procurable from Peruvian balsam and from urine, 1532.

Bergman's account of the cause of

chemical solution, 193. Differences between him and Kirwan accounted for, 435. His method of finding the proportion of ingredients in alum, 644. His account of the quantity of these ingredients, 646. His account of the Swedish ores of alum, 651. His analysis of the ores at Tolfa in Italy, 657. His directions for the preparation of alum, 661. His remarks on the proper form of the coolers for alum, 678. Considers the lapis ponderosus or tungsten as a metallic earth, 967. His opinion concerning the acids of tungsten and molybdæna, 972. Denies the solubility of siliceous earth in acids, 1070. Forms crystals of flint artificially, 1072. Shows the error of those who imagine the explosion of aurum fulminans to be occasioned by a saline principle, 1116. His theory of the explosion, 1120. His opinion concerning the fulmination of other calces, 1126. His opinion concerning the composition of nickel, 1316. His experiments on platina, 1321. Letter to Morveau on the subject of a new nomenclature, 1559.

Berkenhout's opinion of heat, 56. His division of it into fixed and volatile, 57. See *Heat*.

Berthollet discovers fulminating silver, 1138. Procures the marine acid in a solid state, 785. His new salt resembling nitre, 2d 793. How to procure this salt in quantity, 1487.

Bestucheff's tincture of iron, 2d 808. Mistakes of chemists concerning it, 3d 808. True method of preparing it, 4th 808. Supposed to absorb phlogiston from the sun's rays, 5th 808.

Bile: some of its properties assumed by blood when mixed with the nitrous acid, 1477.

Bismuth: Of its precipitation from acids, 241. Copper and bismuth precipitate one another alternately from the nitrous acid, 357. Is scarcely soluble in vitriolic acid, 491. Increases the fusibility of tin and lead, 543. A compound of this kind fusible in boiling water, 544. Dissolved in great quantities by nitrous acid, 765. Volatile alkalies, after precipitating the metal take it up again, ib. The same thing happens with fixed alkalies calcined with inflammable matter, ib. Magistery of bismuth prepared by adding water to the nitrous solution, 766. Neuman's observations concerning this preparation, ib. Effects of acid of arsenic upon it, 952. Is convertible into litharge and glass, 1250. Occupies less space when in fusion than when in a solid state, 1250. Miscible with all the metallic substances except cobalt and zinc, 1251. Promotes the fusion of all the metals with which it is mixed, 1251. Platina may be alloyed with it, but without any advantage, 1348.

Bittern, a kind of salt prepared from it, frequently supercedes the use of the true Glauber's salt, 632. How to

- to procure the marine acid from it, 736.
- Bitumens* particularly treated of, 1441. Whether they are of a vegetable or mineral origin, *ib.* Macquer's opinion that they are only vegetable resins altered, *ib.* Dr Lewis's reasons for being of a contrary opinion, *ib.*
- Black, Doctor*, his theory of heat, 35. Experiments by which he was led to the discovery of latent heat, 41. His method of calculating the quantity of heat produced by the condensation of vapour, 44. Difference betwixt his calculations and those of Dr Crawford, 51. Expansive force of water in freezing explained by Dr Black's theory of latent heat, 108. His experiments on the conversion of water into vapour, 121. His observations on chemical vessels, 557. His directions for performing the operation of solution, 565. Description of his portable furnace, 2d 602. How it is adapted to the various operations of chemistry, 603. Of the luting proper for the inside of this furnace, 604. Method of applying the lute, 605. His account of the preparation of nitre, 724. His conclusions concerning the nature of that salt, 732. His method of making nitrous ether, 775. Shows a method of making it without any spirit of wine, 777.
- Black-lead*, a valuable material for some chemical vessels, 562.
- Bleaching*, how performed by means of dephlogisticated spirit of salt, 1484.
- Blood*, strangely altered in its properties by mixture with nitrous acid, 1477.
- Boerhaave's* experiments to produce a change on mercury by keeping it long in a gentle heat, and by repeated distillations, without success, 1229, 1230.
- Bohemia*: Bergman's account of the aluminous ores in that country, 658.
- Boiling-point* of water in vacuo determined by Mr Boyle, 122. And by Mr Robinson of Glasgow, 123.
- Bole*: camphor converted into an essential oil by distillation with it, 1423.
- Bolognian stone*, a kind of native phosphorus, 1081. How first discovered, *ib.* Margraaf's account of the appearance of this stone, *ib.* How rendered luminous, 1082. Seems to be of a gypseous nature, 1081, 1083. Analysis of it, and reason of its shining in the dark, *ib.*
- Borax*, composed of a peculiar kind of acid and mineral alkali, 863. How prepared in the East Indies, *ib.* Of its state when first imported from thence, 864. How refined, *ib.* Said to be adulterated during this operation, *ib.* This denied by Dr Black, *ib.* Simple dissolution and filtration all that is necessary, according to him, for the purification, *ib.* Its purification according to others, 1490. Has a glutinous quality, by which it gives a gloss to silks, *ib.* Its properties with acids and various salts, 865.
- Borax*, acid of, found in a kind of mineral in Germany, 858. Procured from the salt either by sublimation or crystallization, 858. Is fixed in the fire, and melts into a kind of glass by a violent heat, 860. Dissolves in spirit of wine, *ib.* Makes no change on the colour of vegetable juices, *ib.* Mr Bourdelin's experiments on its nature, 861. Mr Cadet's experiments, 862. M. Beaume's opinion that it is produced by rancid oils unsatisfactory, *ib.* Of its combination with alkalies, *ib.* Forms an unknown salt with vegetable alkali, *ib.* And borax with the mineral alkali, 863. Its effects on cobalt, 1303. Beaume's observations on the method of preparing the sedative salt from it, 1491. Properties of the salt, 1492. Its combinations with volatile alkali, earths, and metals, *ib.* Experiments with a view to determine the nature of the acid, 1493.
- Boulduc*, M. with Geoffroy, discovers the component parts of alum, 641.
- Boullanger's* opinion that the fluor acid is no other than the marine combined with an earthy substance, 833. Shown to be erroneous by Mr Scheele, 834.
- Bourdelin's* experiments on the nature of the acid of borax, 861.
- Boyle*, Mr, improves the science of chemistry, 17. His opinion concerning the number and nature of the elements, 24. Attempts to prove that fire is not an element, *ib.* That the solid substance of bodies is converted into air, *ib.* That water is converted into earth, *ib.* His arguments inconclusive, *ib.* His account of the production of heat, 30. Determines the boiling point of water in vacuo, 122. His experiment showing the destructibility of gold, 1098. Curious kinds of mercury prepared by him, 1227.
- Brass*, how prepared from copper and calamine, 1154. May be reduced to copper again by a long continued and violent heat dissipating the zinc, *ib.* A compound of brass and platina a proper material for speculums, 1344.
- Burning*: phenomena of it, 516. A great quantity of water produced from oil by burning, *ib.* Part of this probably from the atmosphere, *ib.*
- Butter* of antimony composed of regulus of antimony and marine acid, 821. Becomes fluid by rectification or exposure to the air, *ib.* Lets fall the pulvis algaroth by the direct affusion of water, *ib.* Formerly used as a caustic, *ib.* M. Dollfus's method of preparing it, *ib.*
- Butter* of arsenic, prepared from regulus of arsenic and corrosive sublimate, 823. Becomes fluid by repeated rectifications, *ib.* Is not obtained from white arsenic and corrosive sublimed together, 946. May be prepared also by subliming orpiment and corrosive sublimate, 1281. Can scarcely be made to unite with marine acid, 1282.
- CABBAGE*, an excellent test for acids or alkalies prepared from it, 1550.
- Cadet's* experiments on the nature of the acid of borax, 862.
- Calcareous earths*. Decomposition of vitriolated tartar by their solutions explained, 270. Mr Kirwan's experiments on them, 437. Form gypsum with vitriolic acid, 635. Dissolve in the nitrous acid into an acid liquor which cannot be crystallized, 747. Decomposes this acid by frequent distillations, 784. Are convertible by it into a kind of phosphorus, 749. Form likewise a phosphorus with the marine acid, 797. Their effects on the solution of silver, 756. Form astringent compounds with the acetic acid, 871. Decompose cream of tartar, 887. Have a great attraction for saccharine acid, 900. Compose fluor spar by being combined with its acid, 831. And tungsten with the acid extracted from it, 971.
- Calces* of metals; arguments against the existence of phlogiston from the reduction of those of the perfect metals without addition, 140. Reduction of metallic calces by inflammable air, 149. Different colours exhibited by them, 192. Those of some metals, when prepared by nitrous acid, almost totally insoluble ever afterwards, 196. Why little or no elastic fluid is produced from them, 213. Of their attraction to phlogiston, 326. How to find the specific gravity of the different metallic calces, 327. Whence their various degrees of affinity to phlogiston may be determined, 328. Calces of copper precipitate dephlogisticated solutions of iron, 343. Solutions of the dephlogisticated calces of iron refuse to crystallize, 457. Calces of iron precipitated of a reddish colour from spirit of salt, 463. Calces of gold soluble in the vitriolic and nitrous acids, 483. Reason of the increase of weight in metalline calces, 524. Bergman's opinion concerning the fulmination of metallic calces, 1126. Erroneous, *ib.* Effects of the colouring matter of Prussian blue on metallic calces, 1192.
- Calcination*: quantity of phlogiston lost by metals during that operation, 332. Of the affinity of their calces to the deficient part, 332. Calcination of metals by fire described, 522. Of their calcination and increase of weight by acids, 523. Reason of this increase, 524. Solubility of metals increased by calcination, 545. How to perform the operation of calcination, 583. Why a slight calcination destroys the explosive property of aurum fulminans, 1124. Effects of violent calcination on nickel, 1307.
- Calcined metals*. See *Calcination*, *Calces*, *Calx*, and *Metal*.
- Calculus*, human; Scheele's experiments on it, 1455. His conclusions concerning its composition, 1456. Is found universally in urine, 1457. Bergman's experiments on it, 1460. Calcareous earth contained in it separated by means of the vitriolic acid, 1462. Red colour of the solution in nitrous acid accounted for, 1460. Mr Higgins's experiments, 1463. His account of its component parts, 1465, 1468. Experiments on the sublimate arising from it on distillation, 1465. Experiments with nitrous acid, 1466. Crystallization of the nitrous solution by exposure to the sun, 1467. Remarks on the remedies proper for dissolving the stone, 1469. Sublimate of calculus met with in consumptive and gouty persons, 1470. Dissolution ought not to be attempted when the stone is large, *ib.*
- Calculus*: of the acid obtained from it, 982. All the calculi produced in the human body of the same nature, *ib.* Dissolved by concentrated vitriolic, and by the nitrous acid, but not by the marine acid, *ib.* The acid of calculus produces deep red spots on the skin, 983. Assumes a blood-red colour by evaporation, *ib.*
- Calomel*, a name given to mercurius dulcis several times sublimed, 814. Repeated sublimation no improvement on the medicine, *ib.*
- Calx* of the dissolved metal, with various degrees of phlogiston, contained in metalline solutions, 214. Reasons for believing that metals are reduced to a calx by solution, 215. Increase of attraction betwixt the calx of iron and phlogiston demonstrated, 342. Calx of iron soluble in lixivium sanguinis, 1175. But not when highly dephlogisticated, 1176.
- Camphor*, a volatile substance belonging to the class of essential oils, 1422. Converted into a true essential oil by repeatedly distilling it with bole, 1423. Into an acid salt by distilling it several times with dephlogisticated spirit of nitre, 1424. Effects of this salt on alkalies and metals, *ib.* How distinguished from acid of sugar, *ib.* Account of the method of extracting it from the trees which produce it, its uses, &c. *ib.*
- Canton's* phosphorus, how prepared, 1414. Becomes luminous by exposure to the sun, or the light of an electrical flash, *ib.*
- Capacities* of bodies for containing heat: that phrase explained, 52. How they are to be distinguished from the temperature and absolute heat of bodies, 53. The capacity of a body for containing heat the same with the action of heat on the body, 111. Nicholson's account of the capacities of bodies for containing heat, 113.
- Cast-iron* scarcely decomposes the solution of copper, 345.
- Cavalle's* method of purifying ether, 2d 722. Shows that pyrophorus is not injured by exposure to light, 1418.
- Cavendish*, supposes heat not to be a distinct substance, 69. His calculation of the quantity of fixed air con-

contained in impure vegetable fixed alkalis, 417. Shows that nitrous acid may be artificially produced from a mixture of dephlogisticated and phlogisticated air, 2d 722. His opinion concerning the nitrous acid, 1474.

Cautic alkali, how prepared by Mr Bergman for his experiments on the precipitation of metals, 232. Platina imperfectly precipitated by caustic alkali, 234. Throws down a brown precipitate from solution of silver, 235. Corrodes stoneware, 595 [596]. Is best refilled by silver, *ib.* How to prepare lunar caustic, 752. Spirit of wine converted into vinegar and water by repeated distillations with caustic alkali, 1015. The common fixed alkalis composed of a caustic salt and fixed air, 1020. Throws down an insoluble precipitate from solution of terra ponderosa, 1056.

Causivity supposed to be occasioned by the attraction of phlogiston from the substance acted upon, 219.

Cawek, a kind of spar, the same with spathum ponderosum, forms a regulus of animony instantaneously, 1256. Dr Withering's description of a substance of this kind found in Derbyshire, 1068.

Cerufs, or *White-lead*, how prepared, 875. Observations on the process for preparing it, 376. Its poisonous qualities, *ib.*

Chalk at first dissolved, and the solution afterwards coagulated, by acid of arsenic, 936. Flowers of benzoin imperfectly extracted by boiling with chalk, 988.

Chalybeated tartar made by boiling cream of tartar with iron, 895.

Characters, chemical, explained, 551. Some curiously marked on the inside of a phial by means of the light of the sun, 756.

Charcoal proved to be the same with phlogiston, 145. Decisive proofs of their identity from Dr Priestley's experiments, 146. Spirit of wine convertible into charcoal, 147. Charcoal entirely dissipated into inflammable air by the heat of a burning lens *in vacuo*, 148. Dephlogisticated air converted into aerial acid by its union with charcoal, 151. Sulphur produced by distilling concentrated vitriolic acid with charcoal, 715. Or by calcining vitriolated tartar with the same, 716. Arsenical acid takes fire and sublims into regulus with it, 922. Neutral arsenical salt decomposed by it, 926. Charcoal dissolved by liver of sulphur, 1025. Phenomena on distillation with manganese, 1388. Most inflammable matters reduced to charcoal, 1450. Difference between the coals of different substances, *ib.* Some coals, particularly those of animal substances, can scarce be reduced to ashes, *ib.* Bullock's blood affords a coal of this kind, *ib.* Concrete oily substances, or foot, burn with equal difficulty, *ib.* Some of these coals almost resist the action of nitre, *ib.* This substance perfectly refractory, 1451.

How set on fire by the nitrous acid, 1476.

Chemical attraction particularly treated of, 162, *et seq.* See *Attraction*. Bergman's account of the cause of chemical solution, 193. Kirwan's definition of chemical attraction, 260. Difference betwixt it and cohesion, 261. Geoffroy's rule for determining the degrees of chemical attraction, 262. Chemical decompositions apparently single are often double, 263. Invention of chemical marks and characters, 551. New chemical language invented by the French chemists, 552. Its ridiculous appearance in an attempt to explain the fulmination of the calx of silver, 1144. Of tables of chemical affinities or attractions, 553. Dr Black's general table of attractions, *ib.* His observations on chemical vessels, 557. Good and bad qualities of glass as a material for these vessels, 558. Of metals, 560. Of earthen ware, 561. Of chemical furnaces, 599. See *Furnaces*.

Chemistry described, 1. High antiquity of the science, 2. Supposed to be founded by *Siphoas*, an Egyptian, 3. Moses thought to have been well versed in chemistry, 4. Democritus taught chemistry by the Egyptian priests, *ib.* Chemistry introduced into medicine after his time, *ib.* Some advantages accrued to chemistry from the labours of the alchemists, 13. History of chemistry from the time of Paracelsus, 15. The science studied by Lord Verulam, 16. Improved by Mr Boyle, 17. Chemistry emerges from its obscurity, 18. Receives considerable advantages from the founding of the Royal Society, and others of that kind, 19. Great improvements made by chemists of various nations, 20. Perfect theory of chemistry defined, 21. Objects of chemistry how distinguished from the agents, 22. Classification of the objects, 163. How far water is an object of chemistry, 549. Of the different operations in chemistry, 554, *et seq.*

Chemists, improvements by those of different nations, 18, 19, 20. How divided, 555.

Chio turpentine described, 1433.

Cinnabar: of the distillation of it from manganese, 1396. See *Vermilion*.

Clay: whether the earth of alum is to be considered as a pure clay or not, 647. Margraaf demonstrates all clay to be compounded of earth of alum and some other principle mechanically mixed, 648. Experiment of Dr Lewis, which seems to show that clay undergoes a change by being converted into earth of alum, 649. Bergman's experiment to determine the utility of adding clay to the ley of alum in order to absorb the superfluous acid, 682. Advantages of using clay rather than alkalis, 683. Dephlogisticated vitriol decomposed by clay, 684. But not the perfect kind, 685. Clay used in the

the purification of wines, 886. And in that of tartar, *ib.* Combination of arsenical acid with clay, 939. Colouring matter of Prussian blue cannot dissolve clay, 1189. Method of distilling spirit of salt by means of it, 1480.

Cleyborn, Dr: great difference betwixt his calculations and those of Dr Crawford, 48. His opinion concerning the use of thermometers, 72. His hypothesis concerning fire, 74. His proof that fire is an elementary fluid, 81.

Cloth-printing: iron liquor how prepared for that purpose, 873.

Clyffus of nitre, a liquor prepared by deflagrating nitre and charcoal, 780.

Coating of glasses: lute proper for that purpose, 580.

Cobalt: of its dissolution in acids, and precipitation from them, 244. Is not composed partly of iron, 256. Is precipitated by iron, 362. Some heterogeneous matter precipitated from it by nickel, 363. Solutions of cobalt let fall a white powder on the addition of bismuth or copper, 364. Of its solution in vitriolic acid, 496, 710. In nitrous acid, 497. In marine acid, 498. Forms a red solution with the nitrous acid, 769. Discoverable in ores by means of this acid, 770. Forms a beautiful sympathetic ink with marine acid, 822. Dissolved by the acid of arsenic, 954. The semimetal particularly described, and its properties considered, 1293. Its calx, called *zaffre*, described, 1294. Reduction of the calx extremely difficult, 1296. Its properties when exposed to heat, 1297. Calcines spontaneously in the air, 1298. A beautiful blue glass formed from its calx, 1299. Phenomena of it with vitriolic acid, 1300. With nitrous acid, 1301. With marine acid, 1302. With the acid of borax, 1303. With nitre, *ib.* With sal ammoniac, 1304. With sulphur, 1305. May be separated from nickel by nitre, 1311. Method of preparing a red salt from it by means of the vitriolic acid, 710.

Cohesion: difference betwixt it and chemical attraction, 261.

Cold: an excessive degree of it at Glasgow, 62. In Siberia and Hudson's Bay, 63. Severity of the cold in the northern regions mitigated by the production of ice, 87. Heat, light, cold, and electricity, the effects of an universal fluid, 101. Particular solution of the phenomena of heat and cold, 102. Instances of bodies expanding by cold, 105. Cold supposed to be a positive substance from the prodigious expansive force of water in freezing, 107. Dr Cullen's experiments on cold produced by evaporation, 124.

Colour of metallic solutions caused by phlogiston, 218. A beautiful white one from lead, 703. A green one from copper and cream of tartar, 894. How to restore the colour of gold, 1130. Of silver, 1137.

Colouring matter of Prussian blue investigated by Mr Scheele, 1171. This matter flies off from the lixivium sanguinis when exposed to the air, 1172. This effect supposed to be owing to fixed air in the atmosphere, 1173. The colouring matter fixed by the addition of some green vitriol to the lixivium, 1174. Calx of iron soluble in the lixivium, 1175. But not when highly dephlogisticated, 1176. The colouring matter taken up by the air after it has been expelled by acids, 1177. Effects of distilling the lixivium with vitriolic acid, 1178. Attempts to procure the colouring matter by itself, 1179. Neutral salt formed by it for discovering iron in mineral waters, 1180. Effects of distilling this salt with oil of vitriol, 1181. The colouring matter unites with volatile alkali, 1182. How to free it perfectly from any vitriolic taint, 1183. To prevent its escape through the lute during distillation, 1184. The colouring matter neither acid nor alkaline, 1185. Forms a kind of ammoniacal salt with volatile alkali, 1186. Dissolves magnesia alba, 1187. Very little terra ponderosa, 1188. Dissolves lime, but not clay, 1189. This solution most proper for making experiments on metals, 1190. Precipitates the solutions of silver and quicksilver in nitrous acid, and of iron in fixed air, 1191. Its effects on the metallic calces, 1192. On metallic solutions, 1193. Its constituent parts investigated by experiment, 1194. Is of an inflammable nature, 1195. Supposed to contain aerial acid and phlogiston, 1196. Ingredients in its composition, 1199. Unsuccessful attempts to produce it by volatile alkalis in a liquid state, 1200. Successful method with sal ammoniac, salt of tartar, and charcoal, 1201. Its volatility destroyed by manganese, 1204. Can separate only mercury and silver from their solution in nitrous acid, 1205.

Colours of vegetables changed by acids and alkalis, 173. Different colours of metallic calces, 192. Colours imparted to various kinds of stones by solution of silver, 753. Colours of various kinds destroyed by dephlogisticated spirit of salt, 1484.

Comparative heat of bodies defined, 40.

Compost, artificial, of Cramer for making nitre, 728.

Compounds of two metals sometimes heavier than either of the ingredients, 1156. More fusible than either of them singly, 542. Great fusibility of those of tin and bismuth, 543. Fusibility of these augmented by the addition of lead, *ib.* One fusible in the heat of boiling water, 544. Platina unites readily with compound metals, 1343.

Concentrated acids phlogisticated by alkalis, 409. Concentrated nitrous

trous acid dissolves less metal than when diluted, 489. How to obtain a very concentrated acetous acid, 881. Violent action of the concentrated nitrous acid upon molybdena, 960. Marmor metallicum soluble in concentrated vitriolic acid, 1063. Precipitated from it unchanged by vegetable fixed alkali, 1064. Why the concentrated vitriolic acid dissolves manganese without addition, 1378.

Condensation of vapour produces a great quantity of heat, 43, 125. Dr Black's method of calculating it, 44.

Congeaed water, the difficulty with which it melts, a mean of preventing inundations in countries where snow and ice abounds, 88.

Copper: of its precipitates, 238. Why it is dissolved by solutions of silver, mercury, and iron, 336. Why iron and copper precipitate one another, 341. Dephlogisticated solutions of iron precipitated by calces of copper, 343. Dephlogisticates the iron which precipitates it, 344. Its solution scarcely decomposed by cast iron, 345. Why it sometimes cannot precipitate silver, 348. Precipitations of mercury by it, 353. Precipitations of copper by nickel, 360. Copper throws down a white powder from solutions of cobalt, 364. Forms a triple salt with regulus of antimony and marine acid, 367. Precipitates regulus of arsenic from the marine acid, 370. Proportion of it dissolved by the vitriolic acid, 464. Inflammable and vitriolic air produced from its solution in this acid, 465. Quantity of the metal dissolved by nitrous acid, 468. By marine acid, 469. Forms blue vitriol with the vitriolic acid, 693. Of its solution in nitrous acid, 757. In the marine acid, 804. Forms a beautiful green salt with acetous acid, 872. And with cream of tartar, 894. Combination of arsenical acid with it, 947. Forms a most beautiful blue salt with caustic volatile alkali, 1035. Does not greatly diminish the ductility of gold though previously alloyed with tin, 1094. Its nature particularly considered, 1146. Always softer than iron, 1147. Will not strike fire with flint; and therefore of use to make hoops, &c. for gunpowder casks, ib. Its ductility, tenacity, and specific gravity, ib. Explodes violently by the contact of moisture when in fusion, 1148. How granulated, ib. How calcined, 1149. The calx exceedingly refractory, ib. Soluble by all acid and other saline substances, and even by water, 1150. More soluble in cold liquors than in hot, ib. Undergoes some change by combination with vegetable acids, 1151. How amalgamated with mercury, 1152. A curious amalgam formed by mercury and verdigris, 1152. Dr Lewis's methods of amalgamation, 1153. Forms

brass, prince's metal, &c. by the addition of calamine or zinc, 1154. Crucibles in which these operations are performed tinged of a deep blue colour, ib. Forms bell-metal with a mixture of tin, 1155. Lewis's observations on the specific gravity of this and other metallic compounds, 1156. White copper made by fusion with an equal part of arsenic, 1157. A fine gold-coloured metal formed by a mixture of copper and platina, 1341. Phenomena attending the dissolution of it in volatile alkali, 1035.

Copperas. See *Vitriol*.

Corrosive sublimate precipitated without any decomposition by oil of vitriol, 315. May be decomposed by silver in the dry, but not in the moist way, 356. Of its preparation from quicksilver, 814, *et seq.* Differences of its quality according to the different methods by which it is prepared, 816. Reason of these differences, ib. Method of making it at Amsterdam, ib. Observations on the different methods, 817. Of its adulteration with arsenic, 818. Yields no butter of arsenic by sublimation with that substance, 945, 946. Its use in the preparation of butter of antimony, 821. Of its sublimation with manganese, 1397.

Cramer's artificial compost for making nitre, 728.

Crawford, Dr, his explanation of Irvine's theory of heat, 36. Differs greatly in his calculations from Dr Cleghorn, 48. His account of sensible heat, 49. Differs from Dr Black, 51. His opinion concerning heat in the abstract, 54. His definition of fire, 59. His method of determining the proportional quantities of heat in bodies, 77. Insufficiency of his method, 78. His solution of a difficulty concerning the seeming disappearance of heat, 86. Insufficiency, 91.

Cream of tartar, how prepared, 886. Analysed by Mr Scheele, 887. Regenerated, 890.

Crell, Dr, a mistake of his concerning the production of Glauber's salt from alum and common salt corrected, 272. His method of crystallizing the acid of lemons, 997. His attempts to bring vinegar nearer to the state of tartar, 1004. His proofs that all vegetable acids are to be derived from one origin, 1006.

Crocus metallorum, how prepared, 1265.

Cronstedt discovers the new semimetal called nickel, 1306.

Crucibles: of the most proper materials for them, 585. Achard's method of making them from calx of platina, 587. Mr Pott's directions for making them, 588. Dr Lewis's observations on their construction, 589. Porcelain probably the fittest material for vessels of this kind, 591. Of Reaumur's porcelain as a material for crucibles, 592.

Crust produced by the fluor acid on

the surface of water, 828. Found to be of the nature of siliceous earth, 829. Scheele's experiments to determine the nature of this earth, 830. The same crust produced from artificial fluor, 831. Scheele's opinion that the earth is formed by the union of the acid and water, 832. Contested by Messrs Boullanger, Monnet, &c. 833. Their opinions shown to be erroneous by Mr Scheele, 834. Wiegand's experiments on the origin of it, 839. Found to proceed from the corrosion of the glass-distilling vessel, 840. How to procure the acid free from it, 842. None formed by mixing sand with a salt containing fluor acid, 844. But a great quantity by adding powdered green glass, 845.

Crystalline powder thrown down from solution of calx of platina by vegetable fixed alkali, 1325.

Crystallization, in chemistry: how to perform that operation, 573. Crystallization of alum impeded by vitriolic acid, 681.

Crystals of one kind of salt contain none of any other, 573. Fulminating crystals, 1142. Crystals of platina decomposed by the mineral, but not by the vegetable, fixed alkali, 1322.

Cullen, Dr, his experiments on the production of cold by evaporation, 124.

Cupellation: why lead is useful in that operation, 331. Attempts to refine platina by cupellation, 1355.

Cuprum ammoniacale, how prepared, 1034.

DECOMPOSITIONS, chemical, are often double, though apparently single, 263. Explanation of those effected by acids alone, 266. Decompositions of vitriolic salts supposed to arise from compound forces, 276. Why decompositions are sometimes incomplete, 405, 406.

Deflagration, an operation in chemistry, how performed, 582.

Democritus taught chemistry by the Egyptian priests, 4. Said to be able to imitate the precious stones, particularly the emerald, ib. Was probably only acquainted with the method of making green glass, ib.

Density of mixtures, its increase accounted for, 374. How to determine the accrued density of spirit of nitre mixed with water, 387. Increase of it in compound substances, 404.

Dephlogisticated air converted into aerial acid by charcoal, 151. Objection to the existence of phlogiston from the total combustion of it in some cases, 152. Little phlogiston consumed by the combustion of iron in this kind of air, 153. Of the dephlogisticated marine acid, 206, 790, *et seq.* 1484. Dephlogisticated green vitriol cannot precipitate solution of gold, 226. Quantity of mineral alkali taken up by dephlogisticated nitrous acid, 432. Solution of dephlogisticated calx of iron

cannot be crystallized, 457. Dephlogisticated green vitriol decomposed by clay, 684. Dephlogisticated air a material for the nitrous acid, 2d 722. How to prepare the dephlogisticated spirit of salt, 790, 791. Can scarcely be condensed into a liquid, 792. Its other properties, ib. Acid of arsenic procured by its means, 919, 1274. The only solvent of platina, 1319. Dephlogisticated spirit of nitre decomposes camphor, 1424.

Dephlogisticated spirit of salt: expeditious method of bleaching linen by means of it, 1484. Effect of it on phlogistic matters, 1485. Effervesces with caustic volatile alkali, 1485. Forms marine ether with spirit of wine, 1486. Dissolves phosphorus, ib. Method of procuring a detonating salt in quantity from it, 1487.

Diabolus metallorum, a name for tin, on account of its bad effects on other metals, 1222.

Diaphoretic antimony, how prepared, 1264.

Digester, Papin's, described, 567. Effects of it producible by long boiling, ib.

Digestion, in chemistry, how performed, 565.

Digestive salt: Quantity of ingredients in it, 379, 421. Prepared from vegetable alkali and marine acid, 794.

Dissolution of metals: heat produced by that operation, 190.

Distillation: how that operation was originally performed, 6. Mr Watt's experiments on the distillation of water *in vacuo*, 45. Proper method of performing the operation of distillation, 574. Phenomena on distillation of inflammable substances, 517. Boerhaave's experiments on the distillation of mercury, 1230.

Distilled verdigris, how prepared, 872.

Divalent affinities explained, 267.

Dollfus, Mr, his method of preparing butter of antimony, 821. His process for muriatic ether, 824. For acetous ether, 884.

Du Fay supposes all calcareous stones to be phosphoric, 1084.

Dyeing: the vitriol formed by precipitating copper with iron less proper for this purpose than that made after the common method, 344.

EARTH: water supposed to be convertible into it, 24. Has not the character of an element, 25. Soluble in acids, 176. Why the metallic earths seldom decompose salts whose basis is a calcareous earth or alkaline salt, 304. Quantity of earth in vegetable alkali, 413. Difficulty in obtaining the pure earth of alum, 645. Lewis's experiment to show that clay undergoes some change by being converted into this earth, 649. Siliceous earth found in the resin produced from the residuum of vitriolic ether, 2d 722. Quantity of siliceous earth carried up by fluor acid, 847. Earth of alum combined with arsenical acid, 938.

938. Siliceous earth most completely precipitated by volatile alkali, 1074. Forms a triple salt by precipitation with fixed alkali, 1075. Is dissolved by boiling with alkali, 1076. See *Siliceous*. Vegetable earth supposed by Lewis to be the same with magnesia, 1088. Mr Gmelin's experiments on it, 1089.

Earths, how divided, 6th 510. Vitriolic acid combined with different earths, 635, *et seq.* Nitrous acid combined with them, 746. Solution of silver decomposed by calcareous earths, 755. Characters curiously marked by the sun's light on the precipitate, 756. Marine acid combined with earths, 797. Fluor acid with them, 852. Acetous acid, 871. Acid of tartar, 893. Of phosphoric earths, 1081. Earths do not attract the colouring matter of Prussian blue, 1169.

Earthen ware: of its properties as a material for chemical vessels, 561.

Earthy crust. See *Crust*.

East Indies: of the method of preparing nitre there, 724.

Eau de luce, how prepared, 1037.

Effervescence attends the solution of metals, 188.

Educoration, a chemical operation, how performed, 571.

Edinburgh: a kind of ponderous spar, or marmor metallicum, found near that city, 1061.

Elastic fluids extricated during the solution of metals, 189. Great quantity of elastic fluid generated by the explosion of aurum fulminans, 1123.

Elasticity occasioned by heat, and not phlogiston, 209.

Electric attractions, in chemistry, defined, 177. Precipitation of metals by one another owing to a double one, 229.

Electric fluid, in winter, the same with the heat sent down from the sun in summer, 99.

Electric spark produces nitrous acid in a mixture of dephlogisticated and phlogisticated air, 2d 722. Its effect on a mixture of alkaline and dephlogisticated air, 1551.

Electrical heat, why so much stronger than that of furnaces, 160. Capable of vitrifying platina, 1335.

Electricity: proofs of the identity of its fluid with fire and light, 96. Connection betwixt it and fire or heat, 97. Excessive electricity of the polar regions, 98. Electricity, heat, light, and cold, are to be looked upon as the effects of one universal fluid, 101. Explosion of fulminating silver probably owing to it, 1146.

Elements: the supposition of them the origin of alchemy, 23. Mr Boyle's opinion of them, 24. Are in their own nature invisible, 26.

Emetic tartars: different degrees of their strength as commonly prepared, 1258. Pulvis algaroth the most proper material for their preparation, 1259.

Empyreumatic acids produced by dry distillation of vegetables are all of one nature, 995. An acid of this

kind produced from the liquor in which selenites tartarous is boiled, 1010.

Empyreumatic oils, how rectified, 1426.

England: alum-works when erected there, 640.

Engraving on glass, how performed by means of fluor acid, 2d 857.

Eolipile may sometimes be used for blowing up fires, 609.

Epsom salt: proportion of ingredients in the common kind, 443. In nitrous Epsom, 444. Cannot be found in marine Epsom, 445. The true Epsom salt found in the ley remaining after the crystallization of alum, 688. Prepared from the bittern of sea salt, 690.

Equilibrium of heat defined, 75.

Essential salt of lemons, a kind of tartar extracted from sorrel, 838. Essential acids produced from the juices of vegetables, their properties, 994. Phosphorus combined with essential oils, 1412. Analysis of essential oils, 1419. Their taste supposed to be owing to a disengaged acid, 1420. Why they lose their solubility in spirit of wine by being frequently distilled, 1421. Converted by strong heat into empyreumatic oils, *ib.* A considerable quantity yielded by all the kinds of turpentine, 1437.

Ether, vitriolic, produced by a combination of vitriolic acid and spirit of wine, 717. Mr Beaumé's method of making it, 718. Is the lightest of all liquids, 719. Boils *in vacuo* at 20° below 0 of Fahrenheit, *ib.* Produces a great degree of cold by its evaporation, *ib.* Dissolves gold, *ib.* An inflammable salt produced by Wallerius by combining ether with salt of tartar, 720. This thought to be a proof of the transmutation of vitriolic into nitrous acid, *ib.* The phenomenon otherwise accounted for, 721, 722. Mr Cavallo's method of purifying ether, 2d 722. A resin producible from the residuum of its distillation, affording vitriolic, phosphoric, and acetous acids, Glauber's salt, selenite, iron, and earth of flint, *ib.* Nitrous ether produced by combining that acid with spirit of wine, 775. Dr Black's method of making it, *ib.* Mr Woulfe's process for procuring it in large quantity, 776. Inquiry into the nature of ether, 777. Made by Dr Black without any spirit, *ib.* Marine ether how produced, 824. Acetous ether, 884. Saccharine ether, 902. Vitriolic ether crystallizes gold, 1129. Dölsfus's method of preparing it with marine acid, 824. With acetous acid, 884. Methods of Pelletier and others for rectifying vitriolic ether, 1471.

Ethereal solution of gold, its properties, 1129.

Evaporating vessel in alum-works described, 674.

Evaporation: Dr Cullen's experiments on the production of cold by it, 124. Of the method of performing that operation in chemistry, 572. Lead vessels most proper

for evaporations in the large way, *ib.*

Expansion, one of the general effects of heat, 65. That of mercury and some other fluids proportional to the degrees of heat, *ib.* Instruments for measuring the expansion of bodies, 103. Instances of bodies being expanded by cold, 105. Expansion of water in freezing occasioned by the extrication of air-bubbles, 109.

Expansive force of water excessive in the act of freezing, 106. Used as an argument for the positive existence of cold, 107. Explained by Dr Black's theory of latent heat, 108.

Explosion of fulminating gold vastly superior to that of gunpowder, 1108. A small degree of heat sufficient to make this substance explode, 1110. Instances of its mischievous effects, 1112. Its force is not entirely directed downwards, 1113. Of the explosion of moist aurum fulminans, 1114. Not occasioned by a saline principle, 1115, 1116. Nor by fixed air, 1118. Mr Bergman's theory of its cause, 1120. Occasioned by volatile alkali, 1121. Explosion by the vapours of mercury, 1231.

Explosions, violent, occasioned by heat suddenly applied, 722.

Fat, acid of; how procured from suet, 2d 1015. Salts formed by combining it with alkalis, 3d 1015. With earths, *ib.* With metals, 4th 1015.

Fats of animals analysed, 1428.

Fermentation: milk capable of a complete one, 979.

Filings of iron grow hot and take fire spontaneously with sulphur, 1207.

Firmicus Maternus the first writer on alchemy, 8.

Filtering large quantities of water, a scheme for, 569.

Filtration: how to perform that operation in chemistry, 568.

Fire supposed by Mr Boyle not to be an element *per se*, 24. The contrary opinion now generally embraced, 32. Two general theories of it in esteem at present, 33. In what they differ from the theory of Boyle and Newton, 34. Fire detained in bodies partly by attraction and partly by the pressure of the surrounding fluid, 55. Berkenhout's division of fire into fixed and volatile, 57. Pure or volatile fire described, 58. Dr Crawford's definition of fire, 59. Mr Kirwan's opinion, 68. Mr Cavendish's opinion that it is not a distinct substance, 69. Seems destitute of gravity and *vis inertiae*, 93. Proofs of its identity with light and electricity, 96. Connection betwixt fire and electricity, 97. Vitriolic acid contains more fire than the nitrous or marine, 278. Acids unite to alkalis by giving out fire, and quit them by receiving it, 286, 289.

Fixed air: its specific gravity determined, 411. Of the quantity of it in vegetable alkali, 414. In

impure vegetable alkali, 417. Of the quantity contained in mineral alkali, 434. Earth of alum contains a great quantity, 446. Of the quantity of phlogiston in fixed air, 2d 505. Alkaline salts composed of a caustic salt and fixed air, 1020. Is not the cause of the explosion of aurum fulminans, 1118. Expels the colouring matter from lixivium sanguinis, 1173. Water impregnated with it dissolves manganese, 1371.

Fixed alkali less attracted by nitrous acid than silver, 301. Vegetable fixed alkali takes up an equal quantity of all the acids, 402. Exact calculation of the quantity of acid taken up by vegetable fixed alkali, 419. Stone ware corroded by the caustic fixed alkali, 595. Fixed sal ammoniac the same with a combination of the marine acid and calcareous earths, 797. Combination of fluor acid with fixed alkali, 4th 850. Fixed alkaline salts how procured, 1016. Vegetable alkali crystallized in various ways, 1017. Changed by combination with marine acid, 1018. Combination of fixed alkalies with sulphur, 1021. With expressed oils, 1026. With essential oils, 1027. With phlogiston, 1028. Differences observed betwixt those obtained from different vegetables, 1029. Precipitate solutions of terra ponderosa, whether in their mild or caustic state, 1054. The caustic fixed alkalies throw down an insoluble precipitate from these solutions, 1056. Marmor metallicum precipitated unchanged from oil of vitriol by mild vegetable alkali, 1064. A triple salt formed by fixed alkalies, siliceous earth, and fluor acid, 1075. The mineral, but not the vegetable, fixed alkali decomposes crystals of platina, 1322.

Flints, earth of, supposed to undergo a transmutation by being dissolved in an alkaline liquor, 1069. This change denied by Mr Bergman, 1070. The supposed transmutation found to arise from an admixture of clay, 1071. Crystals of flint produced artificially by Mr Bergman, 1072. Why the fluor acid will not dissolve flint directly, 1073. Earth of flints most completely precipitated by volatile alkali, 1074. Forms a triple salt with fluor acid and fixed alkali, 1075. Dissolved by boiling in an alkaline liquor, 1076. Has a remarkable attraction for alkaline salts in the dry way, 1077. Is very rare and spongy when precipitated, 1078. Why the alkaline solution sometimes cannot be precipitated by an acid without heat, 1079. Liquor of flint's decomposed by too great a quantity of water and by fluor acid, 1080. See *Siliceous earth*.

Flores martiales, how prepared, 808.

Flowers of Benzoin, how prepared, 984, *et seq.* See *Benzoin*. Flowers of zinc prepared by the deslagration of that semimetal, 1241.

Dr

- Dr Lewis's method of reducing them, 1242. An oil supposed to be obtained from them by Mr Homberg, 1243. His mistake detected by Neumann, ib. Another oil by Mr Hellot, 1244. Gold and silver leaf dissolved by this oil, ib. A great proportion of nitre alkalized by the flowers of zinc without any sensible deflagration, 1249.
- Flowers*: method of preparing tests for acids and alkalis from them, 1552.
- Fluid*: Dr Cleghorn's proof that heat is occasioned by one, 82. Difficulties concerning the nature and properties of this fluid, 83. Heat most probably the action of an omnipresent fluid, 92. Sensible heat always produced by the conversion of a fluid into a solid, 116.
- Fluidity* occasioned by the absorption of heat, 115, 119. A proof of this from its being possible to cool water below 32° without freezing, 117.
- Fluids* differ in the degrees of absolute heat they contain, 46. The thinnest fluids contain the greatest quantity of heat, 47. Mr Watt's experiments on the evaporation of fluids in *vacuo*, 126. Fluids part with more heat than solid bodies can, 212.
- Fluor acid*: why it can be reduced into air without any addition, 207. First discovered by Mr Margraaf, 826. Prepared by distilling fluor spar with oil of vitriol, 827. Forms a white earthy crust on the surface of water put into the receiver, 828, *et seq.* See *Crust*. Fluor acid proved to be distinct from that of sea-salt, 835. And from the acid of vitriol, 836. Quicklime proved to be the basis of fluor spar, 837. Mistake of M. Monnet on this subject, 838. Wiegand's experiments on the earth contained in this acid, 839, 840. Meyer's examination of the acid, 841. How to procure the acid free from siliceous earth, 842. Experiments for this purpose with an iron distilling vessel, 843. A salt containing fluor acid forms no crust by being mixed with sand, 844. But a great quantity with powdered glass, 845. Of the quantity of siliceous earth which fluor acid carries along with it, 847. Violent action of it upon glass, 848. Mr Wenzel's experiments on the fluor acid in a leaden retort, 850. This acid procurable by means of the acids of nitre, sea-salt, and phosphorus, 2d 850. Appearance and properties of it, 3d 850. Of its combination with fixed alkali, 4th 850. With volatile alkali, 851. With earths, 852. With metals, 853. Glass corroded by it and by the salt produced by its combination with volatile alkali, 854. Great difficulty of preserving this acid, 855. Golden vessels, or a phial lined with oil and wax, recommended for this purpose, 856. Dr Priestley's method of converting the fluor acid into air, 857. Retracts his opinion of its being only the vitriolic acid altered, ib. Fluor acid cannot be expelled by that of arsenic, 934. Why it cannot dissolve flint directly, 1073. Why it decomposes liquor of flints, 1080. Is scarce capable of dissolving manganese, 1366. Explanation of its action on manganese, 1383.
- Fluxes*: platina and some of its calces fusible by their means, 1337.
- Fontana's* account of the specific gravity of different kinds of air, 375. An experiment of his confirming those of Mr Kirwan, 394.
- Fossil alkali*. See *Mineral*.
- Fourcroy* denies that platina can be amalgamated with mercury, 1350. Inconsistence in his account of its hardness, 1351.
- Fragility* of glass when not well annealed, 559.
- France*: of the method of making nitre there, 731.
- Freezing*: of the prodigious expansive power exerted by water during that act, 106.
- Friktion* makes aurum fulminans explode without any heat, 1111.
- Fulminating* calx of silver made by Kunckel, 756. Fulminating copper, 1035. Fulminating gold, 1103. See *Aurum fulminans*. Fulminating silver made by M. Berthollet, 1138. How prepared, 1139. See *Silver*. Fulminating quicksilver, how prepared, 3d 905.
- Fumes*: nitrous and sulphureous effervesce with one another, 626. Gold not rendered brittle by the fumes of tin, 1093.
- Furnace*, a portable one described, 600. Form of Boerhaave's portable furnace, ib. Another described, ib. Dr Lewis's portable furnaces, 601. Objection to their use in some cases, 602. Dr Black's furnace, 2d 602. How adapted to the various operations of chemistry, 603. Luting proper for it, 604. Method of applying the lute, 605. Melting furnace, 2d 605. Mr Pott's melting furnace, 606. Why its cavity is made of a roundish form, 607. Lewis's lamp, 611. One constructed on the principles of Argand's lamps, ib.
- Furnace* necessary for the operations of chemistry, 599, *et seq.* Directions for building them properly, 610.
- Fusibility* of metals increased by mixture, 542. Great fusibility of mixtures of tin and bismuth, 543. Increased by the addition of lead, ib.
- Fusion*: how to perform that operation in chemistry, 534. Difference betwixt the watery and dry fusion, ib. Of the crucibles necessary for the fusion of chemical subjects, 585, *et seq.* See *Crucibles*. Fusion of all metals promoted by bismuth, 1251.
- GARHYTTAN, in Sweden: Rinman's method of burning the aluminous ore there, 668. Method of lixiviating it, 670.
- Galls*, acid of, how separated from them, 1537. An acid liquor procured from them by distillation, 1538. Its properties, 1539.
- Gastric juice* of animals contains phosphoric acid, 904.
- Geoffroy's* rule for determining the degrees of chemical attraction, 262. His table of affinities, 553. Investigates the constituent parts of alum, 641. His theory of Prussian blue, 1165.
- Germany*: method of making nitre in some parts of it, 730.
- Glasgow*: a kind of spathum ponderosum found in its neighbourhood, 1060.
- Glass*: method of engraving on it by means of fluor acid, 2d 857.
- Glass vessels*, when to be used by chemists, 556. Dr Black's remarks on the properties of glass, 558. Affords the siliceous crust observed on fluor acid, 840. Violent action of that acid on glass, 848. Corroded by it and by the ammoniacal salt produced from it, 854. Bismuth convertible into glass, 1250. How to prepare glass of antimony, 1257. A beautiful blue glass produced by the calx of regulus of cobalt, 1299.
- Glass of lead*: of the vessels most capable of resisting its action, 589.
- Glass-making*: Pliny's account of the origin of it, 7.
- Glasses*: of the materials proper for coating them, 580.
- Glauber's sal ammoniac* prepared from vitriolic acid and volatile alkali, 633. See *Ammoniac*.
- Glauber's salt*: Dr Crell's mistake concerning its preparation from alum and common salt, 272. Its decomposition by marine acid never complete, 291. Reason of this decomposition explained, 306. Quantity of ingredients in it, 431. Prepared from vitriolic acid and mineral alkali, 632. Dangerous consequences of mistaking crystals of nitre for it, 743. Produced from the resin extracted from the residuum of vitriolic ether, 2d 722.
- Glauber's spirit of nitre*, 734.
- Gmelin*, Dr, his experiments on the differences betwixt the alkaline salts produced from different vegetables, 1029. On the ashes of different plants, 1089. Method of making dulcified spirit of salt, 1481.
- Gold*: why its solution is precipitated by green vitriol, 225. But not by the dephlogisticated kind, 226. Why it is precipitated by solution of tin, 227. Various precipitates of it, 233. Best kind of aqua regia for dissolving it, 481. Quantity of it taken up by aqua regia, 482. Its calces soluble in the vitriolic and nitrous acids, 483. Kirwan's opinion that the metal cannot in any quantity be dissolved in the nitrous acid, 484. Dr Brandt's experiments, showing that it may be so in close vessels, 750. Lewis's observation on this experiment, ib. Solution of its calces in spirit of salt, 799. Sublimes along with the acid, ib. The sublimate said to be the material used for the blood of St Januarius, 800. Is not affected in any way by the arsenical acid, 941. Its nature and properties particularly treated of, 1089. Unites readily with all the metals, 1090. Its colour debased by all the metals except copper, ib. Said to lose its malleability remarkably with tin, 1091. Dr Lewis's account of the bad effects of this metal upon it, ib. Mr Alchorne's experiments in opposition, 1092. Gold not rendered brittle by the fumes of tin, 1093. Nor by the addition of the metal itself in small quantities, ib. Nor with the addition of copper, 1094. Malleability of gold entirely destroyed by a small quantity of regulus of arsenic, 1095. Surprising tenacity of its parts, 1096. Is not liable to rust, 1097. Mr Boyle's experiment to show its destructibility, 1098. Of its solution in aqua regia, 1099. This solution of a corrosive nature, 1100. May be crystallized, ib. Of the precipitation of the metal from it, 1101. Separated from other metals by green vitriol, 1102. Explodes with prodigious force in some cases, 1103—1126. See *Aurum fulminans*. Solution of gold by hepar sulphuris, 1127. Medical virtues of gold entirely imaginary, 1128. Solution in essential oils not permanent, 1128. Dissolved permanently in ether, and crystallizable by its means, 1129. Revived from its solution in aqua regia by mixing it with spirit of wine, ib. A method thus afforded of purifying it from other metals, ib. How to restore its colour when lost, 1130. Mercury fixed by amalgamation with gold, 1234. Whether it be possible to adulterate gold with platina, 1356. How to detect this fraud if it should be practised, 1357.
- Golden calf*: its dissolution adduced as an instance of Moses's skill in chemistry, 4.
- Golden sulphur of antimony*, how prepared, 1263.
- Golden vessels* recommended for keeping the fluor acid, 856.
- Granulation of copper*, how performed, 1148.
- Gravity*: the element of fire seems to be destitute of it, 93. Of finding the specific gravity of the different metallic calces, 327. How to find the specific gravity of bodies, 371. Of the specific gravity of spirit of salt, 377. How to find that of the ingredients in digestive salt, 380. Of the pure nitrous acid, 386. Of its mathematical specific gravity, 388. How to construct a table of the specific gravities of spirits of nitre of different strength, 390. How to find the specific gravity of pure vitriolic acid, 397. Of the acetic acid, 400. Of strong vinegar, 401. Of fixed air, 411. Of fixed vegetable alkali, 412. Mr Watson's account of the specific gravity of salt of tartar, 415. Dr Lewis's observations on the specific gravity of bell-metal and other metallic compounds, 1156.

Green colour produced from verdigris and cream of tartar, 894.

Gun-powder: its explosive force vastly inferior to that of aurum fulminans, 1108.

Gypsum: proportion of ingredients in the natural kind, 439. Formed of the vitriolic acid and calcareous earth, 635. Some differences betwixt the natural and artificial kinds, ib. Is soluble in some degree by acids, 636. Convertible into quicklime by a strong heat, ib. Fused by a very violent and sudden heat, and likewise by the addition of clay or calcareous earth, ib. Decomposed by fixed and mild volatile alkalis, ib. And by the acid of arsenic, 933. Found in the concentrated vitriolic acid, 1059.

HANOVER: method of making nitre there, 729.

Hafiz: of the aluminous ores found in that country, 658.

Heat, two general theories of, 28. Lord Bacon's definition of it, 29. Mr Boyle's opinion, 30. Sentiments of Sir Isaac Newton on the subject, 31. Fire or heat generally allowed to be an element *per se*, 32. Two other theories instituted, 33. In what they differ from the former, 34. General account of Dr Black's and Dr Irvine's theory, 35. Dr Irvine's theory explained by Dr Crawford, 36. Absolute heat defined, 37. Great quantity of heat produced by the condensation of vapour, 43, 125. Difference of the absolute heat of different fluids, 46. Thinnest fluids contain the greatest quantity of it, 47. Crawford's account of sensible heat, 49. Capacities for containing heat explained, 52. Crawford's opinion concerning heat in the abstract, 54. Dr Berkenhout's opinion of its nature, 56. Heat has a tendency to diffuse itself equally over bodies, 60. Is contained in considerable quantities in all bodies, 61. Its quantity limited in all bodies, 64. Expansion an universal effect of heat, 65. Bodies of the same kind and of equal temperature contain quantities of heat proportioned to their quantities of matter, 67. Equilibrium of heat defined, 75. Dr Crawford's method of determining the proportional degrees of heat, 77. His method insufficient, 78. Nicholson's account of the theories of heat, 79. Advantages of the doctrine that heat is caused by vibration, 80. Answer to Mr Nicholson's argument, 81. Dr Cleg-horn's proof that heat is occasioned by a fluid, 82. Difficulty arising from the supposition that heat diffuses itself equally, 84. Another from the seeming disappearance of heat, 85. Equal distribution of heat promoted by its absorption and evolution, 89. Heat of the torrid zone thus mitigated, 90. Heat most probably the action of an omnipresent fluid, 92. Distribution of heat occasioned by the action of the sun, 94. How heat

is produced by his rays, 95. Connection between heat and electricity, 97. Heat in summer becomes electric fluid in winter, 99. Solution of the phenomena of heat, 102. Mr Kirwan's theorem for finding the point of total privation of heat, 114. Heat the cause of the softness of bodies approaching to fluidity, 118. Absorption of heat the universal cause of fluidity, 120. Heat produced in the burning of inflammable bodies comes from the air, 157. Too much phlogiston prevents the heat of burning bodies from being intense, 158. Why the solar heat and that of electricity are so intense, 160. Table of the various degrees of heat, 161. Heat produced during the dissolution of metals, 190. Heat and not phlogiston the cause of elasticity, 209. Heat produced in solution most probably proceeds from the solvent liquor, 211. Argument in favour of the weight of precipitates being augmented by the matter of heat, 249. Experiments to determine the cause of some chemical decompositions from the degrees of heat produced by various mixtures, 277. Alteration of the density of acids by various degrees of heat, 423. Strong spirit of nitre more expanded by heat than weak, and why, 424. Dilatation of spirit of salt by various degrees of heat, 427. What metals are calcinable, and by what degrees of heat, 530. Violent explosions from the sudden application of heat, 722. Effects of heat on lapis ponderosus, 969. Mercury unalterable by being kept 15 years in a gentle heat, 1229.

Hellot procures from flowers of zinc an oil capable of dissolving gold and silver leaf, 1244.

Hepar sulphuris formed by a combination of fixed alkalis and sulphur, 1021. May be made either in the moist or dry way, 1021. Partly decomposed by fixed air, ib. Entirely by acids, 1022. Effects of the inflammable vapour arising during its decomposition, ib. 1023. Its phlogiston very much disposed to fly off, 1024. Dissolves many metals, and charcoal, 1025. Solution of gold by its means, 1127. Its effects of it upon nickel, 1309.

Hepatic air contains sulphur, 210.

Hermes Trismegistus, the same with Siphaoas, an Egyptian, the founder of chemistry, 3.

Higgins, Mr, his experiments on human calculus, 1463, *et seq.* His observations on the nitrous acid, 1472. Method of obtaining it quite colourless, 1475. Discovers the true composition of volatile alkali, 1553.

Homburg's experiments on specific gravities compared with those of Kirwan, 392. Different results of them accounted for, 393, 399. An oil obtained by Homburg supposed to come from the flowers of zinc, 1243. The mistake discovered by Neumann, 1243. How he discovered his pyrophorus, 1415. Best method of preparing it, 1416. See

Pyrophorus. Discovers that marine acid corrodes glass, 1482.

House-painting: a yellow colour for that purpose, 699.

JANUARIUS, St., a sublimate of marine acid and gold shown for his blood, 800.

Ice: a quantity of heat lost in the melting of it, 42.

Jelly, the mucilage of animal substances, 1454. All of them reducible to this by long boiling, ib. Is the only true animal substance, ib. Forms a very strong cement, ib.

Ignited bodies all equally hot, 128.

Ignition an universal effect of fire, 130. Difference betwixt ignition and inflammation, 132.

Ilex aquifolium: the growth of that plant a sign of aluminous ores in the ground, 639.

Inflammable and vitriolic acid air obtained from solution of copper in vitriolic acid, 465, 471. Inflammable substances, their nature and properties, 516. Principles into which they are resolved by burning, ib. By distillation, 517. Their phenomena with different acids, 518. Some singular productions, 519. Vitriolic acid combined with them, 712, *et seq.* Nitrous acid, 771, *et seq.* Marine acid, 824. An inflammable spirit extracted from sugar of lead, 878. Inflammable vapour arising from the decomposition of hepar sulphuris, 1023. Volatile alkalis combined with them, 1035. Of their division and chemical properties, 1398, *et seq.*

Inflammable air: metallic calces reduced by it, 149. Revival of lead from minium by it, 324. Quantity of inflammable air produced from iron, 454. Why none is produced from the nitrous solution of iron, 460. Charcoal entirely convertible into it, 1451.

Inflammable spirit produced from radical vinegar, 1544. Sulphureous inflammable vapours produced from it, 1545.

Inflammation: difference betwixt it and ignition, 132. Bodies decomposed but not destroyed by inflammation, 133.

Ink: a fine sympathetic one produced from solution of cobalt in spirit of salt, 822. Another by means of volatile tincture of sulphur and saccharum saturni, 1039. Blue sympathetic ink prepared from cobalt, 822.

Insoluble precipitate thrown down by caustic fixed alkali from solution of terra ponderosa, 1056.

Inundations prevented by the slowness with which congealed water melts, 88.

Iron: objection to the existence of phlogiston from the total consumption of dephlogisticated air in burning it, 152. Little phlogiston expelled from it by this means, 153. The objection inconclusive, 154. This metal not reduced to a calx by burning in dephlogisticated air, 155. Water produced in the reduction of it by inflammable air, 156. Of its precipitates by different substances, 239. Is not an essential ingredient in platina, 254.

Nor regulus of nickel, 255. Nor cobalt or manganese, 256. Why solutions of iron dissolve copper, 336. Iron and zinc the only metals dissolved by vitriolic acid, 337. Why copper and iron precipitate one another, 341. Increase of the attraction of calx of iron to phlogiston demonstrated, 342. Dephlogisticated solutions of iron precipitated by calces of copper, 343. Why a saturated solution of silver can scarce be precipitated by iron, 346. Of the precipitation of zinc and iron by one another, 347. Iron and nickel will scarcely precipitate one another, 359. Cobalt precipitated by iron, 362. A triple salt formed by iron, regulus of antimony, and marine acid, 366. Proportion of iron taken up by the vitriolic acid, 453. Why vitriolic air is produced by dissolving iron in concentrated vitriolic acid, 455. Solution of the calces of iron in vitriolic acid, 456. That of the dephlogisticated calces refuses to crystallize, 457. Proportion of iron dissolved in nitrous acid, 458. In the marine acid, 462. Calces of iron assume a red colour when precipitated from their solution in the marine acid, 463. Produces green vitriol by combination with vitriolic acid, 696, 697. Precipitates spontaneously from the vitriolic acid, 698. Iron contained in the resin produced from the residuum of vitriolic ether, 2d 722. Cannot be dissolved by concentrated, though it will by diluted, nitrous acid, 759. Dissolves and produces inflammable air with marine acid, 805. Volatilized by this acid, 806. Its solution used in medicine, 807. Combined with acetous acid, 873. With acid of tartar, 895. With the acid of arsenic, 948. Its nature and properties particularly treated of, 1157. Has great tenacity of parts, 1158. Is a combustible substance, 1159. Is the only metal capable of being welded, 1160. Contracts in fusion, and expands again on becoming cold, 1161. Is dissolved by all metals except lead and mercury, 1162. Becomes brittle by being immersed for some time in that fluid, 1162. Can scarce be united to zinc, ib. Has a strong attraction for arsenic, ib. Is the basis of Prussian blue, 1163, *et seq.* See *Prussian blue*. Calx of iron soluble in lixivium sanguinis, 1175. Neutral salt for discovering it in mineral waters, 1180. Precipitated by the colouring matter of Prussian blue from its solution by aerial acid, 1191. Nitre alkalized by it, 1206. Its filings take fire spontaneously with sulphur, 1207. Unites with platina, 1347.

Iron liquor for printing cloth, how prepared, 873.

Irvine, Dr: general account of his and Dr Black's theory of heat, 35. His theory explained by Dr Crawford, 36.

Italy: of the first alum-works set up there, 639.

Juice, gastric, yields phosphoric acid, 904.

KEIR, Mr, his objections to the doctrines of Mr Kirwan, 2d 510. His method of preparing an alkaline standard, 4th 510. Of finding the specific gravity of different liquors, 5th 510. His objections to the opinions concerning the identity of the vegetable acids, 1540.

Kermes mineral, how prepared, 1263.

Ketley, in Shropshire: a kind of spathum ponderosum found there, 1060.

Kilpatrick-hills, near Glasgow: spathum ponderosum found there, 1060.

Kirwan's opinion concerning fire, 68. His theorem for finding the point of total privation of heat, 114. His remarks on some experiments of Dr Priestley, 325. His experiments compared with those of Homberg, 392. Different results of their experiments accounted for, 393, 399. Kirwan's experiments confirmed by one of Fontana, 394. Differences with Mr Bergman and Lavoisier accounted for, 435. Is of opinion that gold cannot be dissolved in nitrous acid, 484. Mistake of Morveau concerning a superabundance of acid in alum accounted for, 642. Objections to his doctrine concerning the specific gravity, &c. of different substances, 2d 510, *et seq.* To his calculation of the quantity of phlogiston in sulphur, 6th 510.

Kunkel prepares a fulminating calx of silver, 756.

LAMP FURNACE: Dr Lewis's described, 611. Is not capable of giving a greater heat than 450° of Fahrenheit, *ib.*

Language: specimen of a new chemical one, 552. Its strange appearance in attempting to account for the phenomenon of fulminating silver, 1144.

Lapis ponderosus considered as a metallic earth by Mr Bergman, 967. See *Tungsten*.

Latent heat: experiments by which Dr Black was led to the discovery of it, 41. This heat cannot be measured, 73. Expansion of water in freezing explained by the theory of latent heat, 108. Air bubbles in ice produced by part of the latent heat of the water, 110. Vapour formed by the absorption of heat into a latent state, 120.

Lavoisier denies the existence of phlogiston, 137. His arguments drawn from the increased weight of metals by calcination, 138. His theory of inflammation, 139. His arguments from the reduction of the calces of perfect metals without addition, 140. Dispute betwixt him and Priestley, 141. His differences with Kirwan accounted for, 435. Account of some of his experiments on the increased weight of metallic solutions, 525. Consequences deduced by him from these experiments, 526. Not well founded, 527. Account of the

constituent parts of the nitrous acid, 1473. His new nomenclature, 1560.

Lead: quicksilver produced from it in certain cases, 12, 762. Water may be made sufficiently hot to melt lead, 131. Why the vitriolic acid cannot act upon it without a boiling heat, 197. Precipitates of lead, 237. Sea-salt decomposed in various ways by means of it, 302. In what cases solution of lead is precipitated by other metals, 309. The solution in marine acid decomposed by vitriolic salts, 310. Revival of lead from minium by inflammable air, 324. Why it is useful in cupellation, 331. Precipitation of it by nickel, 360. Vessels capable of resisting the glass of lead, 589. Lead vessels most proper for the preparation of oil of vitriol, 627. Cannot be dissolved in the vitriolic acid, 702. A beautiful white for painting in water prepared from litharge, nitrous and vitriolic acids, 703. Dissolves and crystallizes with the nitrous acid, 761. This salt decrepitates with great violence in the fire, 762. Becomes fluid like oil by repeated dissolutions in aquafortis, 762. Combination of lead with marine acid, 811. Plumbum corneum, 812. Combined with acetous acid, 874. White lead the result of this preparation, 875. Observations on the process for making it, 876. Sugar of lead prepared from acetous acid and white lead, 877. Inflammable spirit procured by distilling this salt, 878. Combination of lead with the acid of arsenic, 949. Great attraction betwixt silver and lead, 1136. Cannot be united to iron, 1162. The metal particularly treated of, 1207. *et seq.* The least ductile and tenacious of all metals, 1208. Sheet-lead, how cast, 1209. Milled lead scarce to be preferred to this kind, 1210. Rendered sonorous by being cast into a certain shape, 1211. Of its calcination, 1212. Minium or red-lead, how prepared, 1213. Litharge, 1214. Phenomena with other metals, 1215. Remarkable way of uniting with copper and separating from it again, *ib.* Soluble in alkalies and oils, 1216. Of its union with platina, 1348.

Lemons, essential salt of, a species of tartar extracted from sorrel sold under this name, 888. Dr Crell's method of crystallizing the acid of lemons, 997. This acid cannot be converted into acid of sugar, 999. Entirely dissolves manganese, 1370. Explanation of the action of the acids of tartar and lemons on manganese, 1382.

Levigation, a chemical operation, how performed, 599. Reaumur's porcelain recommended for levigating utensils, *ib.*

Lewis, Dr, his observations on the making of crucibles, 590. His experiments on Reaumur's porcelain, 593, 594. Description of his portable furnaces, 601. Objection

to their use in some cases, 602. His lamp-furnace described, 611. His experiment to show that clay undergoes some change by being converted into earth of alum, 649. His directions for making turbith mineral, 706. Experiments on the solubility of tin in the acetous acid, 880. His opinion concerning the earth of vegetables, 1088. His methods of amalgamating mercury with copper, 1153. His observations on the specific gravity of bell-metal and other compounds of the metallic kind, 1156. His observation on the cracking noise made by tin in bending, 1221. His detection of an erroneous process in which mercury was supposed to be converted into water, 1236. His method of reducing the flowers of zinc, 1242. His experiments on alloying platina with other metals, 1338.

Ley, alkaline, why it is unfit for extracting the flowers of benzoin, 989.

Libavius, smoking liquor of, how prepared, 810.

Lichtenstein's experiments on the acid of benzoin, 1530.

Light: proofs of its identity with fire and electricity, 96. The effect of one universal fluid, 101. Characters curiously marked by the sun's light on a precipitate of silver by calcareous earth, 756.

Lime the most proper material for extracting the flowers of benzoin, 991. Crystallization of the acid of lemons prevented by the smallest particle of lime, 998. Terra ponderosa convertible into a kind of lime capable of decomposing vitriolic salts, 1055. Dissolved by the colouring matter of Prussian blue, 1189. How prevented from sticking to the bottoms of distilling vessels, 1033.

Lime-water precipitated by the arsenical acid, 935.

Liquid phosphorus, how prepared, 1410.

Litharge prepared in the refining of silver with lead, 1214. Almost always contains some lead in a metallic state, *ib.* Bismuth convertible into a substance of this kind, 1250.

Lithifac acid. See *Calculus, acid of*.

Lixivium sanguinis loses its colouring matter by exposure to the air, 1172. Calx of iron soluble in it, 1175.

Liver of arsenic formed of alkali and arsenic boiled together, 1276.

Lubbock, Dr, his theory of heat, &c. 142.

Luna cornea, why it cannot be reduced without loss by alkaline salts, 314. May be decomposed by mercury, 356. How prepared, 802. Its properties gave rise to the notion of malleable glass, 803. How reduced, 1134.

Lunar caustic, how prepared, 752.

Lute, proper for lining furnaces, 605.

Luting for acid spirits, 577.

MACERATION, in chemistry: how to perform that operation, 598.

Macquer's theory of Prussian blue,

1167. Supposes the fusion of calx of platina by the methods recommended to be imperfect, 1354.

Magnesia combined with vitriolic acid, 690. With acid of arsenic, 937. Dissolved by the colouring matter of Prussian blue, 1187. Will not dissolve in acids after calcination without heat, 442. Its preparation and properties, 514. Combined with the nitrous acid, 749.

Magistery of bismuth, 766.

Manganese: how to dephlogisticate spirit of salt by it for the decomposition of arsenic, 919. Combined with the arsenical acid, 936. Identity of vegetable acids proved from the solution of manganese by the nitrous acid with the addition of acid of sugar, 1011. From its solution by means of vitriolic acid and spirit of wine, 1114. Keeps the colouring matter of Prussian blue from rising, 1204. A new semi-metal afforded, 1359. Common manganese treated with vitriolic acid, 1360. Is entirely dissolved by phlogistigated vitriolic acid, 1361. Precipitate and crystals obtained from the solution, 1362. Dissolved by phlogistigated nitrous acid, 1363. Effects of it on spirit of salt, 1364. See *Dephlogistigated and Marine acid*. Entirely dissolved by marine acid, 1365. Scarce soluble in fluor acid, 1366. Or in that of phosphorus, 1367. Partly dissolves in acid of tartar, 1368. With difficulty in the acetous, 1369. Entirely dissolved by acid of lemons, 1370. And by water impregnated with fixed air, 1371. Has a strong attraction for phlogiston, 1372. Becomes white by saturation with it, 1373. Contains some phlogiston naturally, 1374. Becomes insoluble in pure acids by losing its phlogiston, 1375. Partial solutions of manganese explained on this principle, 1376. Its strong attraction for phlogiston when combined with acids, 1377. Why it is dissolved by the concentrated acid of vitriol without addition, 1378. Why the volatile sulphureous acid dissolves it, 1379. Explanation of the effects of nitrous acid upon it, 1380. Of those of tartar and lemons, 1382. Of fluor acid, 1383. Effects of manganese on nitre, 1384. Experiments of manganese united with phlogiston, 1385, *et seq.* By distillation *per se*, 1386. Boiled with oil-olive, 1387. By distillation with charcoal, 1388. With sulphur, 1389. By calcination with nitre, 1390. With the addition of arsenic, 1391. By distillation with sal ammoniac, 1392. By digestion with pure nitrous acid, 1393. Destroys volatile alkali by attracting its phlogiston, 1394. Effects of distilling it with arsenic, 1395. With cinnabar, 1396. With corrosive sublimate, 1397. Used for the rectification of ether, 1471.

Margraaf's analysis of all the different

rent kinds of clay, 648. His experiments on the phosphoric acid, 906. His method of reducing luna cornea, 1134. His process for making phosphorus with plumbum corneum, 1407. Experiments with phosphorus on metals, 1413. Method of procuring the acid of ants, 1502.

Marine acid, the weakest of the three mineral acids, except when dephlogisticated, 183. Why it acts on some metals and not on others, 198. Phenomena exhibited by the marine acid on account of its naturally containing phlogiston, 205. Dephlogisticated marine acid examined, 206. Vitriolic salts decomposed by a marine acid, 275. Contains less fire than the vitriolic acid, 278. On its expulsion by the concentrated vitriolic acid, 283. Receives fire from the vitriolic acid during its expulsion, 284. Decomposes vitriolated tartar, 288. Requisites for the success of the experiment, 289. Cannot decompose vitriolated tartar previously dissolved in water, and why, 290. Decomposition of Glauber's salt and vitriolic ammoniac by marine acid never complete, 291. Nitrous salts decomposed by marine acid, 292. Cannot decompose selenite, 294. Solution of silver constantly decomposed by salts containing marine acid, 308, 312. Vitriol of mercury decomposed in the same manner, 313. Nitrous acid has less affinity with metals than the marine, 338. In what cases marine acid can dissolve metals and when it cannot, 340. Forms a triple salt with iron and regulus of antimony, 366. And with regulus of antimony and copper, 367. Arsenic precipitated from marine acid by copper, 370. Quantity of marine in digestive salt, 379. Of mild and caustic vegetable alkali saturated by marine acid, 382. Quantity of mineral alkali saturated by it, 433. Of the quantity of marine acid saturated by calcareous earth, 438. Quantity of acid in marine selenite, 441. Cannot be calculated in marine Epsom, 445. Quantity of earth of alum saturated by marine acid, 450. Quantity of iron dissolved by it, 462. Calces of iron precipitated from it of a reddish colour, 463. Quantity of copper dissolved by it, 469. Tin dissolved in marine acid, 473. Lead dissolved in it, 477. Of the dissolution of silver in it, 480, 801. Solution of zinc in marine acid, 490. Bismuth scarce soluble in it, 493. Solution of nickel in it, 495. Regulus of antimony scarce soluble in marine acid, 505. Why the marine acid acts so weakly, 510. Its nature and combination with other substances particularly treated of, 782. Most commonly found combined with the mineral alkali, ib. Why it is thought by some to be the same with the vitriolic, 783. An experiment tending to make this observation probable, 784. Dr

Priestley's observations on marine acid, 785. How procured by means of the vitriolic, 786. Why its distillation with copperas does not succeed, 787. To procure marine acid by means of the nitrous, 788. By distilling common salt *per se*, 989. Marine acid dephlogisticated by that of nitre, or by manganese, 790. Mr Scheele's method of dephlogisticating it by manganese, 791. Properties of it when dephlogisticated, 792. Marine acid combined with alkaline salts, 793. With vegetable fixed alkali, 794. With mineral alkali, 795. Volatile alkali, 795, 796. Combined with earths, 797. With metallic substances, 799. Dissolves and volatilizes the calx of gold, ib. With silver, 801. Dissolves the red silver ore, ib. Forms luna cornea with this metal, 802, 803. With copper, 804. With iron, 805. Volatilizes this metal, 806. The solution of iron in this acid used in medicine, 807. Sublimate of iron, and sal ammoniac named *flores martiales*, 808. Solution of tin, 809. Of great use in dyeing, ib. Volatilizes the metal, and forms with it the smoking liquor of Libavius, 810. With lead, 811. Forms with it plumbum corneum, 812. With quicksilver, 813. Forms with it corrosive sublimate, 814, *et seq.* See *Corrosive*. Volatilizes zinc, 820. With regulus of antimony, 821. See *Butter*. Forms a fine sympathetic ink with regulus of cobalt, 822. Combined with inflammable substances, 824. Marine ether, 824. Of its attraction for phlogiston, 825. Is not the same with fluor acid, 835. Expels the fluor acid, 2d 850. Purifies salt of amber, 911. Phenomena on dissolving vitriolic salts in marine acid, 1041. On mixing them with solutions of calcareous earth in marine acid, 1042. Of the solution of terra ponderosa in it, 1053. Is not necessary for the preparation of aurum fulminans, 1117. Solution of cobalt in marine acid, 1302. Effects of manganese upon it, 1364. Existence of phlogiston in it proved, 1381. Can scarcely unite with butter of arsenic, 1282. Dephlogisticated marine acid the only solvent of platina, 1319. Used for distillation of spirit of nitre, 737. Various methods of making marine ether, 824. Method of distilling the acid with clay, 1480. Effect of it upon phlogistic matters, 1481. Glass corroded by it, 1482. Cause of its yellow colour, 1483. Effect of the dephlogisticated acid upon phlogistic matters, 1485. How to make marine ether from the dephlogisticated acid, 1486.

Marks, chemical, treated of, 551. *Marmor metallicum*, Withering's experiments on it, 1060. Dissolves in concentrated vitriolic acid, 1063. Precipitated from it unchanged by vegetable fixed alkali, 1064. May be decomposed in the dry

way by salt of tartar, 1065.

Martial vitriol, procured by precipitating copper with iron, less fit for dyeing than the common, 344.

Marrow analysed, 1430.

Mathematical specific gravity explained, 373. The mathematical specific gravity of spirit of nitre determined, 388.

Mayer's examination of the fluor acid, 841, &c.

Melting furnace described, 2d 605, *et seq.* See *Furnace*.

Mensurum, a quantity of it retained by some precipitates, 251.

Mensurum sine strepitu, a liquor for dissolving gold, 1119.

Mercurius dulcis, how prepared from corrosive sublimate, 814, 819. Preparation of it in the moist way, 1238.

Mercurius precipitatus per se, how prepared, 1228.

Mercurius Trismegistus, the same with Hermes or Siphos, an Egyptian, the founder of chemistry, 3.

Mercury, of its precipitates, 236. Its solution in nitrous acid decomposed by vitriolic salts, 311. Vitriol of mercury decomposed by marine acid, 313. Why corrosive mercury is precipitated by oil of vitriol, 315. Examination of Dr Priestley's experiment concerning the revival of mercury, 322. Why so much of the metal was revived in the Doctor's experiments, 323. Why copper is dissolved by solution of mercury, 336. Precipitations of mercury by copper, 353. Why mercury and silver precipitate one another from the nitrous acid, 355. Corrosive sublimate cannot be decomposed by silver, though mercury can decompose luna cornea, 336. Why precipitates of mercury and alum contain part of the acid, 408. Of mercury dissolved in vitriolic acid, 485, 704. See *Quicksilver*. Copper, how amalgamated with mercury, 1152. Dr Lewis's methods, 1153. A curious amalgam with verdigris, ib. Cannot be united with iron, 1162. May be separated from its solution in nitrous acid by the colouring matter of Prussian blue, 1203. Uses of the amalgam of mercury and tin, 1223. The metal particularly described, 1225. Is sensibly heavier in winter than in summer, ib. How purified, 1226. Curious mercuries prepared by Mr Boyle, 1227. Is calcined into a red powder, by being exposed to a considerable degree of heat, and to the air at the same time, 1228. Is unalterable by a gentle heat, or by repeated distillations, 1229, 1230. Explosion by its vapours, 1231. Amalgamated with different substances, 1232. Separation of the amalgamated metal, 1233. Becomes fixed by amalgamation with gold, 1234. Supposed to be convertible into water, 1235. The mistake detected by Dr Lewis, 1236. How to amalgamate it with regulus of antimony, 1237. Can scarce be united with platina, 1345. Will leave platina to

unite with gold, 1346.

Metallic calces, of their various colours, 192. Metallic solutions contain a calx of the metal with various degrees of phlogiston, 214. Phlogiston the cause of their colour, 218. Some metallic salts decompose others, 224. Advantages to be derived from the examination of metallic precipitates, 253. Metallic salts insoluble in water without an excess of acid, 297. Of the attraction of metallic calces to phlogiston, 326. Of finding their specific gravity, 317. Table of the proportional affinities of metallic calces to phlogiston, 329. They can never be totally dephlogisticated by acids, 407. Of their general properties, 519. Are soluble in acids, 520. Composed of an earth and phlogiston, 521. Their calcination and revivification, 522. Increase of weight by acids, 523. Reason of the increase of weight in metallic calces, 524. Combinations of them with acids. See *Acid and Metals*. Lapis ponderosus supposed by Mr Bergman to be a metallic earth, 967. Why he supposed the acids of molybdena and tungsten to be metallic earths, 973. Chemical properties of the different metallic substances investigated, 1089, *et seq.* Effects of the colouring matter of Prussian blue on metallic calces, 1192. Its effects on metallic solutions, 1193.

Metals may receive a vast quantity of heat more than is sufficient to bring them into a state of fusion, 129. The calces of the perfect ones reducible without addition, a proof of the nonexistence of phlogiston, 140. Why they weigh less in their metallic than in their calcined state, 150. Combine with acids, 176. Separate from them again on the addition of earths or alkaline salts, 177. Phenomena attending their solution in acids, 180. Of their different degrees of solubility, 185. Their solution attended with effervescence, 188. And heat, 190. Yield little air after they have been calcined, 191. Why marine acid acts on some of them and not on others, 198. Why some metals are more soluble than others, 199. Their solutions contain a calx of the dissolved metal, 214. Reasons for believing that this calcination takes place, 215. Why the calces of the perfect metals may be reduced without addition, 216. Phenomena attending the precipitation of metals by alkaline salts, 220. Their precipitation by one another owing to a double elective attraction, 229. Variations in the order in which they precipitate one another, 230. They contain different quantities of phlogiston, 258. Difficulties in determining the attractive powers of the metals to acids, 296. Quantities of the different metals taken up by acids, 298. Metals have a greater affinity than alkalies with the acids, 299. Why alkalies precipitate the metals, 300. Why th

the metallic earths seldom decompose salts having an earth or alkali for their basis, 304. Explanation of the table of affinities of the acids to the different metals, 316. Of the quantity of phlogiston contained in the different metals, 317. Quantity of it lost by metals during calcination, 331. Why the metals are more dephlogisticated by mutual precipitation than by direct solution, 335. All of them dissolved by nitrous acid, 338. In what cases the marine acid can dissolve metals, and when it cannot, 340. Mr Kirwan's experiments on metals, 451. Best method of dissolving them, 452. What metals are calcinable, and with what degrees of heat, 530. Of their rusting, 541. Their fusibility increased by mixture, 542. Their solubility increased by calcination, 545. Effects of sulphur on them, 546. Of their division into metals and semimetals, 547. Their good and bad qualities as materials for chemical vessels, 560. Vitriolic sal ammoniac erroneously supposed to be a great solvent of metals, 634. Effects of vitriolic acid on metals, 691, *et seq.* Of the nitrous acid, 750. Of the marine acid, 799. Of the fluor acid, 853. Of the acetous, 872. Of the acid of tartar, 894. Of the acid of sugar, 901. Of the phosphoric acid, 906. Of the acid of amber, 915. Acid of molybdæna has no sign of any metal, 964. Metals dissolved by hepar sulphuris, 1025. Combination of volatile alkali with metals, 1034. Their properties particularly treated of, 1090. The fusion of all metals promoted by bismuth, 1251. Of the effects of white arsenic on them, 1277. Effects of regulus of arsenic on other metals, 1288. Combination of metals with sulphur, 1403. Effects of phosphorus on them, 1413.

Microcosmic salt, how prepared from urine, 905. Mr Margraaf's experiments on it, 606.

Milk, of its acid, 974. Acquires its greatest acidity by standing a fortnight, *ib.* Scheele's method of procuring the pure acid of milk, 976. Properties of this acid, 977. It seems to be of the acetous kind, 978. Milk is capable of complete fermentation, 979. How to procure the acid of sugar of milk, 980.

Milled lead: the advantages of using it in preference to sheet-lead precarious, 1270.

Mindereri spiritus: how to crystallize it, 1515.

Minium, of the revival of lead from it by inflammable air, 324. How to prepare it from the metal, 1215.

Mineral alkali, why preferred as a precipitant by Mr Bergman, 231. Precipitates platina imperfectly, 234. An equal quantity of all the mineral acids taken up by vegetable fixed alkali. See *Acids*. How to prepare the mineral alkali for experiments on the precipitation of metals, 429. Quantity of it taken up by the dephlogisticated ni-

trous acid, 532. Excess of acid in aluminous ley cannot be removed by mineral alkali, 630. Of its combinations with the different acids. See *Acetous*, *Marine*, *Vitriolic*, &c. Difference between it and the vegetable alkali, 1019. Whether mineral alkali can separate platina from its solvent, 1329. Fifty-six times as much of it required to precipitate this metal as of vegetable alkali, 1329.

Mineral acids. See *Acids*.

Mineral waters: Mr Woulfe's test for them, 1557. See *Waters*.

Mispickel, a natural regulus of arsenic, 1286.

Mixtures: the attractive powers of acids determined by the various degrees of heat excited by them, 277. Increased density of mixtures accounted for, 374. Time required by mineral acids and water to acquire their utmost density, 422. Phenomena resulting from mixtures of the different acids, alkalies, and neutral salts, with one another, 1040, *et seq.*

Molybdæna, acid of, examined, 957. How to reduce the substance to powder, 958. Effects of the acid of arsenic upon it, 959. Violent action of the concentrated nitrous acid upon this substance, 960. Acid of molybdæna procurable by fire alone, 961. Its chemical properties, 962. Is capable of uniting with phlogiston, 963. Shows no sign of containing any metal, 964. Properties of the acid obtained by nitre, 965. Molybdæna recomposed by uniting its acid with sulphur, 966. Differences betwixt the acids of tungsten and molybdæna, 971. M. Pelletier's experiments on this acid, 1497.

Monnet's opinions concerning the fluor acid, 833. Shown to be erroneous by Mr Scheele, 834. Mistake of Mr Monnet concerning the basis of fluor spar, 838.

Morveau's mistake concerning the preparation of Glauber's salt from alum detected by Mr Kirwan, 642.

Moses supposed to be well skilled in chemistry, 4.

Mucilage of vegetables considered, 1452. Of animals the same with jelly or glue, 1454.

Muriatic. See *Marine*.

NAPHTHA, a fine kind of mineral oil described, 1442.

Neumann's observations on the preparation of the magistery of bismuth, 766.

Neutral salts composed of an acid and alkali, 172. One for discovering iron in mineral waters, 1180. Platina may be partly precipitated by some neutral salts, 1331.

Newton, Sir Isaac, his sentiments concerning heat, 31.

Nicholson's account of the theories of heat, 79. Answer to his argument concerning vibration as the cause of heat, 81. His account of the capacities of bodies for containing heat, &c. 113.

Nickel, a kind of semimetal, of its solution and precipitation, 442. Is precipitated by zinc, 358. Iron

and nickel will scarcely precipitate one another, 359. Nickel precipitates copper, lead, and bismuth, 360. Throws down some heterogeneous matter from cobalt, 363. Of its solution in vitriolic acid, 493. In the nitrous acid, 770. Effects of acid of arsenic upon it, 955. The semimetal particularly treated of, 1306. Discovered by Mr Cronstedt, *ib.* Effects of calcination with a violent heat upon it, 1307. Of sulphur and borax, 1308. Of hepar sulphuris, 1309. Of nitre, 1310. This salt separates all the cobalt in the semimetal, 1311. Effects of sal ammoniac upon it, 1312. Of nitrous acid, 1313. Of volatile alkali, 1314. Nickel cannot be obtained in a state of purity, 1315. Bergman's opinion of its composition, 1316. Experiments to compose it artificially, 1317.

Nitre: quantity of acid, water, and alkali in it, determined, 391. Why it is so much lighter than vitriolated tartar, 416. The ingredients of which it is composed, 420. Of the preparation of nitre, 724, *et seq.* Discovered in some places in Podolia in Poland, 725. In Spain and America, 726. Requisites for its formation, 727. Cramer's artificial compost for making it, 728. How prepared in Hanover, 729. In other parts of Germany, 730. In France, 731. Dr Black's conclusion concerning its nature, 732. Supposed to be the last effect of putrefaction, 733. How to procure the spirit of nitre by means of vitriolic acid, 735. Of its rectification, 736. Different methods of distilling, 737. Its uses, 738. Prepared from the nitrous acid and vegetable fixed alkali, 740. Cubic nitre formed from this acid and mineral alkali, 741. Enumeration of its properties and uses, 742, 743. Lavoisier's account of the constituent parts of nitrous acid, 1473. Mr Cavendish's account, 1474. How to set charcoal on fire by means of it, 1476. Remarkable effects of it on blood, 1477. Mr Scheele's experiments with it on various substances, 1513. Volatile alkali prepared from nitrous acid and tin, 1553.

Some late experiments of Dr Priestley have shown, that though nitrous acid is produced from the decomposition of dephlogisticated and phlogisticated air, by taking the electric spark in the mixture, it is likewise produced by the more rapid decomposition of combustion, when inflammable air is made use of instead of the phlogisticated kind. In this case, though phlogisticated air should happen to exist in the mixture, it is not in the least affected by the process, but remains after the combustion of the others just as it was; nay, the Doctor observes, that by the addition of phlogisticated air, the quantity of nitrous acid produ-

ced is so far from being augmented, that it is much diminished. The acid in these processes always appears to be extremely volatile, inasmuch that some part of it constantly escapes. No liquor at all was condensed when the explosions were made in quick succession, even though the vessel never became hotter than the hand. In another process, the atmospheric air was perfectly excluded, while the purest dephlogisticated air was produced from one of the materials employed, viz. precipitate *per se*. In this experiment he found, that a considerable quantity of fixed air was produced, and that the water became acid by the absorption of it. He concludes, therefore, on the whole, that a mixture of dephlogisticated and inflammable air always produces an acid by combustion; but that, when they are in their nascent state, the aerial acid is generated; when both are completely formed previous to the experiment, the nitrous acid appears.

Nitrous air: Why it does not unite with water, 204. Quantity of it produced by solution of iron in nitrous acid, 459. Quantity of phlogiston contained in it, 505. OBJECTS of chemistry, how distinguished from the agents, 22. How classed, 163.

Oil of vitriol precipitates corrosive sublimate from water, and why, 315. Kirwan's experiments on it, 395. Why the dilution of it is necessary in these experiments, 396. Quantity of fixed air in oil of tartar, 414. Why oil of vitriol and iron produce vitriolic air, 455. Combination of oil of vitriol with common oil, 712. Oil of arsenic, how prepared, 823. Canton's phosphorus, 414. Homberg's phosphorus, 1415, *et seq.* See *Pyrophorus*.

M. Pelletier has now discovered a method of uniting phosphorus, without any decomposition, with all the metals, though he cautions against the danger with which the process is attended. Gold is phosphorated by mixing half an ounce of its calx with an ounce of phosphoric glass and about a grain of powdered charcoal; the whole is then put into a crucible, the composition covered with a little powdered charcoal, and a degree of heat sufficient to fuse the gold applied. A great many phosphoric vapours arise, but part are detained, and unite with the gold which is left at the bottom of the crucible. The metal by this operation loses its colour, becomes whitish, breaks under the hammer, and has a crystalline appearance.

appearance. By continuing the fire a long time the phosphorus would be entirely dissipated. The quantity of phosphoric glass and charcoal just mentioned is sufficient to phosphorate a whole ounce of platina. By an hour's calcination in a crucible, the metal is converted into a blackish mass resembling silver, weighing upwards of an ounce, and of which the lower part consists of cubical crystals. Notwithstanding this change, however, the quantity of phosphorus united with the platina is very inconsiderable; for from 12 ounces of the metal, and as much phosphoric glass, only 12 ounces and five grains of the phosphorated metallic mass was obtained. It was very brittle, but of considerable hardness; was not attracted by the magnet, and by exposure to a strong fire parted with the phosphorus it had been combined with. He observes, that all the metals lose their malleability by combination with phosphorus, excepting tin and lead; and the residuum of the matter which has once phosphorated a metal, will serve again for the same purpose.

The salt formed by a combination of the phosphoric acid with mineral alkali is found to be an useful purgative, and as such is now brought into practice.

Messrs Struve and Marquart are said to have discovered, that the gastric juice of animals is composed of the phosphoric acid and volatile alkali; and Mr Struve has composed a liquid from these two ingredients which acts in a similar manner on alimentary matters.

Itcoal analysed, 1447.

Platina not partly composed of iron, 254. An excellent material for chemical vessels, 587. Mr Achard's method of making crucibles of its calx, 587. Effects of acid of arsenic upon it, 942. Is the heaviest of all metals, 1318. Insoluble except by dephlogisticated marine acid, 1319. Found in small grains, 1320. Bergman's experiments on it, 1321. Crystals of it can be decomposed by the mineral, but not the vegetable fixed alkali, 1322. Soluble in aqua regia made with nitrous acid and sea-salt, 1323. In one made of nitre and spirit of salt, 1324. Solution of the calx in marine acid lets fall a crystalline powder on the addition of vegetable alkali, 1325. But not the nitrous solution, 1326. - Sugar*, acid of, the same with that of sorrel, 2d 903. Acid of apples procured from sugar by means of the nitrous acid, 1512.
- The acid procurable from this substance by means of the nitrous, resembles that of tartar, in being capable of supersaturating the vegetable alkali, and forming with it an acid salt resembling crude tartar. This is found naturally existing in sorrel and some other plants. There is, however, another acid obtained from sugar along with an empyreumatic oil by dry distillation, which has been purified and examined by Mr Schrikel. Eight ounces and four scruples of liquid were obtained in this manner from 16 of fine sugar. About six drachms of water came over first; after which the acid passed in unctuous striae on the sides of the receiver. It had a pungent and agreeable smell, and tasted empyreumatic. By repeated distillations from pure clay, its smell became mild, and it acquired an apparent increase of acidity. With vegetable alkali, it formed a salt tasting like that of Sylvius, and shooting into needle-like crystals, soluble with difficulty in cold water, but not at all in spirit of wine. It did not deliquesce in the air; but decrepitated in the fire, and did not melt on hot coals. With the mineral alkali yellow crystals were formed resembling Rochelle salt in taste, easily soluble in water, and not deliquating in the air. Volatile alkali gave a sharp saline liquor, which could not be crystallized, but left a
- saline mass on evaporation; and a similar saline mass was produced by uniting it with calcareous earth. Magnesia and earth of alum formed gummy compounds. When concentrated, it dissolved the calx of gold, and even gold-leaf; but had no effect on silver, mercury, or their calces. With minium it gave a yellow solution, which shot into oblong white crystals of an astringent taste. A blood-red solution, which shot into green crystals, was obtained from iron. Copper was dissolved into a green liquid, which did not crystallize. Regulus of antimony was also dissolved, and the solution was of a greenish colour. Zinc was partly dissolved into a green liquor, and partly corroded. The precipitates were remarkable. The crystals of iron gave a green precipitate with alkalies, a black or dark blue one with Prussian alkali, and a white one with marine acid. Solution of regulus let fall a yellow precipitate with fixed alkali; with volatile alkali, a powder soluble again in the precipitant; vitriolic and marine acids, and an infusion of galls, threw down a white powder, but no precipitate ensued on adding nitrous acid. Solution of zinc gave a white precipitate with infusion of galls, alkalies of all kinds whether fixed, volatile, or phlogisticated, as well as by the vitriolic acid. Tin was partially dissolved, and the solution precipitated by alkalies, and an infusion of galls, but not by any of the mineral acids. Lead was precipitated of a white colour by vitriolic and marine acids, and of a grey colour by infusion of galls.

Schiller's method of procuring its acid, 888.

Though the acid of tartar has been commonly supposed a product of the vinous fermentation, yet late experiments have shown that this is not the case. It has been found not only in the juice of the grape, but in that of tamarinds, the berries of the *rhus coriaria*, and the leaves of the *rumex acetosa*. In these it is generally combined with the vegetable fixed alkali, or with calcareous earth. Hermbstadt has found it combined with calcareous earth in the juice of the roots of the *trilicium repens*, the *leontodon saxatilis*, and *China-bark*. By the assistance of nitrous acid he obtained it also from the juice of grapes, mulberries, apples, pears, oranges, strawberries, and plums; also from honey, sugar, gum arabic, manna, spirit of wine, beech-wood, and the root of black hellebore. In these cases, where the nitrous acid is made use of, however, it may justly be supposed that the acid of tartar is partly at least produced from it. In Scheele's process for procuring the pure acid of tartar by means of calcareous earth, it is advisable to make use of quicklime rather than chalk, as by this double the quantity of tartar will be decomposed. An hundred parts of pure tartar contain about 23 of vegetable alkali, 43 parts of acid employed to saturate that alkali, and 34 of superabundant acid. By using oyster-shells well prepared by boiling and powdering, the crystals of the acid may be obtained very white and pure. Some chemists have imagined that the vegetable alkali does not exist ready formed in tartar, but that it is produced by fire or mineral acids. In proof of this M. Machi offers the following experiments. On an ounce of cream of tartar were poured 10 ounces of boiling water, and the mixture allowed to remain in a jar covered with paper and parchment in which a small hole was made with a pin. At the end of three months it was considerably diminished; and contained a quantity of thick, tough, yellow, mucilaginous matter, which neither effervesced with acids nor alkalis, and, when burnt, the ashes were found to contain only a very small quantity of alkali. The experiment was repeated by Mr Corvinnus with some variation. He kept

a solution of cream of tartar in a heat between 10° and 30° of Reaumur's scale; removing the saline pellicles which formed on the surface as fast as they appeared, and redissolving them in water. By continuing the digestion for several months, the liquor became at last evidently alkaline; and he thus obtained 216 grains of a brown alkali from two ounces of cream of tartar. Mr Berthollet exposed for nine months, to the heat of his laboratory, a solution of two ounces of cream of tartar in eight ounces of water; taking care to replace the water which evaporated, but without removing the crusts which formed upon the surface. At the end of this time he found that the liquor was no longer acid, but began to turn the syrup of violets green. In 18 months it became strongly alkaline; and left, when evaporated, an oily residuum which effervesced with acids, and weighed 468 grains. On treating in the same manner a solution of terra foliata tartari, the liquor began to change the syrup of violets green in two months, and in four the decomposition seemed to be complete. At the end of a year he filtered and evaporated the liquor to dryness, by which process he obtained 432 grains of fixed alkali. The same quantity of terra foliata tartari decomposed immediately by distillation, yielded only 36 grains more of alkali. Solution of salt of wood-ferreffered no decomposition by a similar treatment for two years. The latter he observed to be a much more powerful antiseptic than tartar; for which reason it seems to resist decomposition in a proportionable degree. He supposes oil to be the principal cause of the destruction of these acids; and the obvious deficiency of oil in the saccharine acid, in comparison with tartar, seems to be the cause of the want of capacity in it to undergo the decomposition just mentioned. A remarkable circumstance attends this spontaneous decomposition, viz. that no air is either absorbed or emitted during the whole process. It is also worth notice, that in combining acid of tartar with fixed alkalis, the salt supersaturated with acid or cream of tartar is always formed in preference to the other called *soluble tartar*. Thus, if to a saturated solution of alkali with cream of tartar we add another of pure tartareous acid, a white spongy matter will be precipitated to the bottom; which, on examination, is found to be a true tartar. Any other acid added to the solution of tartarified tartar will in like manner produce a precipitation of tartar, by engaging a part of the alkali with which it was combined; and if the acid of tartar be added to a solution of any neutral salt containing the vegetable fixed alkali, as vitriolated tartar, salt of Sylvius, and nitre, a similar precipitation of tartar will ensue. Hence the acid of tartar may be employed as a test to discover the presence of the vegetable fixed alkali, and to distinguish it from the mi-

neral, which has not that effect. Bergman indeed observes, that Rochelle salt will do the same thing; but it must be remembered, that this is prepared with crude tartar, which contains a portion of vegetable alkali, and not with the pure acid.

Tungsten particularly examined, 967, *et seq.* Considered as a metallic earth by Mr Bergman, 967. Scheele's method of analysing it, 968. Effects of heat upon it, 969. Its chemical properties, 970. Differences betwixt the acids of tungsten and molybdæna, 971. Bergman's opinion concerning them, 972. Why he supposed the acids to be metallic earths, 973. Its properties according to M. Luvart, 1498. Of the yellow matter called its acid by Mr Scheele, 1499. No simple acid procurable from the mineral, 1501. A new semimetal made from it, 1501.

Turbith mineral, how prepared, 705, 706.

Turpentine: Appearance of oil of turpentine with acid of arsenic, 923. Chio turpentine described, 1433. Venice turpentine, 1434. Strasburg, 1435. Common, 1436. Analysis of turpentine, 1437. Essential oil difficult of solution, 1438.

Vapour formed by the absorption of latent heat, 120. Dr Black's experiments on the conversion of water into vapour, 121. Heat expelled in great quantity by its condensation, 125.

Vegetable colours changed by acids and alkalis, 173. Of vegetable earths, 515, 1089. Supposed by Dr Lewis to be the same with magnesia, 1089. Dr Gmelin's experiments,

experiments, *ib.* Vegetable ammoniac, 870. Vegetable ether, 884. Vegetable acids produce a remarkable change on copper, 1151. Vegetable substances in general considered, 1451.

The following is a list of the Vegetables from which the industry of the modern chemists has procured different acids, with the names of the discoverers.

1. *Agave Americana.* The juice exuding from the calyx of this plant yields acid of tartar and apples. Mr Hoffman of Weimar.

2. *Aloes.* Acid of sugar and apples. Mr Scheele.

3. *Apples.* A peculiar acid called by the name of the fruit. By nitrous acid that of tartar is procured. Mr Scheele and Mr Hermstadt.

4. *Barberry.* Acid of apples, and of tartar. By treatment with nitrous acid it yields acid of sugar. Scheele and Hermstadt.—Hoffman denies that it contains any native acid of tartar. By treating it with spirit of wine and manganese he obtained an ether.

5. *Bilberry (Vaccinium myrtillus).* Equal parts of the acids of citrons and apples. Scheele.

6. *Bramble (Rubus chamaemorus).* The same with the foregoing. Scheele.

7. *Campbor.* A peculiar kind of crystallizable acid. M. Kosegarten.

8. *Cherries.* Equal parts of acids of citrons and apples. Saccharine acid by treatment with spirit of nitre. Scheele, Hermstadt, and Westrumb.—Hermstadt says that he found acid of tartar also.

9. *Citrons and lemons.* A particular kind of crystallizable acid. Scheele.

10. *Coffee.* The infusion evaporated and treated with spirit of nitre. Acids of sugar and apples. Scheele.

11. *Corks.* A yellow acid by repeated abstractions of spirit of nitre. With some of the alkalis and earths this acid forms crystallizable salts which do not deliquesce, though others do. That with fixed vegetable alkali forms needle-like crystals, soluble in water, vitriolic, nitrous, or marine acids, but not in vinegar or spirit of wine. Like the saccharine acid it has a strong affinity to calcareous earth, which it separates from lime-water, and forms a greyish saline powder, soluble in marine acid, but not in water, nor even in its own acid. It exhibits some appearances with metals, which deserve farther examination. Brugnatelli.

12. *Cranberry (Vaccinium oxycoccus).* Acid of citrons. Scheele.

13. *Currants, red and white.* Acids of citrons and apples. Westrumb. Hermstadt says that they contain acid of tartar.

14. *Elder berries.* Acid of apples. Scheele.

15. *Galls.* A peculiar kind of acid. Scheele.—Mr Keir observes, that from other astringent matters, especially those used in dyeing, it is probable that similar acids might be obtained. Mr Morveau has obtained from galls a resin which he supposes to be their acidifiable base; and

which, along with pure air, forms the acid of galls. When purified, this acid is said to make a fine and durable ink.

16. *Geranium acidum.* Small acid crystals. Cartheuser. Said by Hermstadt to be the acid of sugar.

17. *Gooseberries.* Acid of apples. Scheele.—Hermstadt says that they contain the acid of tartar also.

18. *Grapes.* Their juice well known to contain the acid of tartar partially combined with fixed alkali.

19. *Grafs-roots.* Saline crystals from the extract of the juice after three months standing. These were soluble in water, and gave an earthy precipitate on mixture with fixed alkali. On abstracting the nitrous acid from them, and adding a solution of calcareous earth in vinegar, a precipitate fell, which was found to consist of acid of tartar saturated with lime. Hermstadt.

20. *Gum Arabic.* Acid of sugar and apples. Scheele.

21. *Gum tragacanth.* Acids of sugar of milk, apples, and sugar.

22. *Haw (Crataegus aria).* Equal parts of acids of citrons and apples.

23. *Honey.* An acid liquor by distillation; and with spirit of nitre, the acid of sugar. The distilled acid has been said to dissolve gold.

24. *Lemons.* An acid the same with that of citrons.

25. *Leontodon taraxacum.* Acid of tartar by treatment with spirit of nitre.

26. *Manna.* Acid of sugar by treatment with spirit of nitre.

27. *Mulberries.* Acid of tartar. Hermstadt. A crystallizable acid salt by evaporating the juice. Angelus Sala.

28. *Oil of olives.* A salt which sublimed and crystallized, by repeated and copious abstractions of the nitrous acid. Westrumb.

29. *Peruvian bark.* Acid of apples and sugar, by treating the extract with nitrous acid. Scheele.

30. *Prunus spinosa et domestica.* Acid of apples. Scheele.

31. *Prunus padus.* Acid of citrons. Scheele.

32. *Poppy.* Acids of sugar and apples, by treating the juice with nitrous acid. Scheele.

33. *Raspberries.* Acids of apples and citrons. Scheele. Acid of tartar by saturating the juice with chalk, and then separating the earthy basis by means of vitriolic acid. Hermstadt.

34. *Rhapontic.* Acid of tartar by crystallizing the juice; of sugar by treating it with nitrous acid. Bindheim.

35. *Rhubarb.* Acids of sugar and apples by treating the infusion with nitrous acid. If a pound of Indian rhubarb be infused in hot water, a powder subsides, which by washing becomes white, weighing then about nine drachms, and is found to consist of calcareous earth united with the acid of sugar. Scheele.

36. *Ribes cynosbati.* Acid of citrons or lemons. Scheele.

37. *Salep.* Acids of sugar and

apples by treatment with nitrous acid. Scheele.

38. *Service (Sorbus aucuparia).* Acid of apples. Scheele.

39. *Solanum dulcamara.* Acid of citrons. Scheele.

40. *Sorrel (Rumex acetosa).* Crystals of tartar by evaporating and crystallizing the juice; and pure acid of tartar by saturating the acid with chalk, and then expelling it by means of the vitriolic. Hermstadt. Other chemists, however, have certainly found it to contain the acid of sugar partly neutralized with alkali, and which is capable of being crystallized. This is generally known under the name of *salt of wood-sorrel*, and is manufactured in considerable quantities in Thuringia, Suabia, Switzerland, and the Hartz. It is prepared from this plant as well as the *oxalis acetosella*. The plants are bruised in stone or wooden mortars; the juice is squeezed through linen; and when cleared by settling, is to be boiled to a proper consistence, and clarified with the whites of eggs, or with blood. It is to be strained whilst hot, and then kept in a cold cellar. In a few weeks crystals will be formed, from which the remaining liquor must be poured off, and by further evaporation will yield more salt. Savary obtained only two ounces and a half of salt from 25 pounds of the juice.

41. *Strawberries.* Equal parts of the acids of apples and citrons. Scheele.

42. *Sugar.* See the article.

43. *Sumach (Rhus coriaria).* Crystals of tartar. Professor Tromsdorf and Son.

44. *Tamarinds.* Acid of tartar, tartar itself, with a mucilaginous and saccharine matter. Westrumb.

45. *Vaccinium vitis idaea.* Acid of citrons. Scheele.

46. *Wood and bark of the birch tree.* From 55 ounces of the wood were obtained 17 ounces of rectified acid, which when freed from an amber-coloured oil was to the specific gravity of water as 49 to 48, and of such strength that one ounce of it required 23 of lime-water for its saturation. Chemists of Dijon.—By allowing the acid distilled from the bark to remain at rest for three months, much of its oil was separated; by saturation with fixed alkali a dark-coloured neutral salt was obtained, which was purified by fusion and subsequent filtration and evaporation. On subjecting the purified salt to distillation, an acid arose, which had no longer an empyreumatic smell, but rather a flavour of garlic. Gaetling. *Vegetations*, curious, produced from solution of silver, 754.

Venice turpentine. See Turpentine.

Verdigris, how prepared, 872. Distilled, *ib.* Verdigris distilled, best method of making it, 872.

Verditer, a preparation of copper, 758. Method of making blue verditer generally unknown, *ib.*

Vermilion made by subliming sulphur and mercury together, 1404. Difficulty in adjusting the proportions of the ingredients, *ib.* May be made without sublimation from

quicksilver and the volatile tincture of sulphur, *ib.* Or with the solution of sulphur by fixed alkali or quicklime, *ib.* Is darker or lighter according to the quantity of sulphur, *ib.*

Verulam, Lord, studies and revives the science of chemistry, 16. His opinions concerning heat, 29.

Vessels, chemical: of the proper ones to be used, 557, *et seq.* Dr Black's opinion, *ib.* Of glass, 558. Of metal, 560. See *Chemical, Glass, Metal, Earthen ware, and Porcelain.*

Vibration: Nicholson's account of the advantages attending the supposition that heat is occasioned by it, 80. Answered, 81.

Vinegar: specific gravity of it when strongly concentrated, 101. Why it may be reduced into air without addition, 208. Procurable from the residuum of vitriolic ether, *ad 722.* Lewis's experiments on the solubility of tin in this acid, 880. Whey convertible into vinegar, 979. Requisites for bringing it nearer the state of tartar, 1002. Westrumb's attempts for this purpose, 1003. Dr Orell's opinion of the possibility of the transmutation, 1004. Method recommended by him for attempting the experiment, 1005. Supposed to be an antidote against arsenic, 1520. Difference between radical vinegar and common acetous acid, 1528.

Vit inertia: fire seems to be destitute of it, 93.

Vitriol: why solution of gold is precipitated by the green kind, 225. But not by this salt when dephlogisticated, 226. That procured by precipitation of copper with iron less fit for dyeing than the common, 344. Blue vitriol cannot be formed by boiling alum and copper filings, 349. Proportion of ingredients in blue vitriol, 467. How to extract green vitriol from pyrites, and to distil the acid from it, 620, *et seq.* Extracted from the same ore with sulphur and alum, 659. Alum is generally contaminated by dephlogisticated vitriol, 684. Perfect green vitriol cannot be destroyed by clay, 686. How to abstract the phlogiston from it, 687. How to prepare blue vitriol, 693. Parts with its acid with more difficulty than the green kind, 694. Its uses, 695. White vitriol, how prepared, 708. Why the distillation of sea-salt with copperas does not succeed, 787. Green vitriol decomposed by saccharum saturni, 1044. Fixes the colouring matter of Prussian blue, 1174. How affected by dephlogisticated marine gas, 1485.

Vitriol, acid of. See *Vitriolic acid.*

Vitriolic acid: why it cannot act on lead, silver, &c. without a boiling heat, 197. Cannot be reduced into an aerial form but by a combination with phlogiston, 202. On the expulsion of the nitrous acid by the vitriolic diluted, 280. By the same in a concentrated state,

state, 281. With a small quantity of vitriolic acid diluted, 282. On the expulsion of the marine acid by the concentrated vitriolic, 283. Decomposition of vitriolic ammoniac by marine acid never complete, 291. Why the vitriolic acid resumes on evaporation the bases it had left, 285. Decomposition of vitriolic ammoniac by solution of silver explained, 306. Of corrosive mercury by concentrated vitriolic acid, 315. Can dissolve no other metals than iron and zinc, 337. Kirwan's experiments on the specific gravity of oil of vitriol, 385. Why it is necessary to dilute the acid in these experiments, 396. To find its specific gravity, 397. Quantity of acid necessary to saturate pure mineral alkali, 430. Why vitriolic air is produced by dissolving iron in concentrated vitriolic acid, 455. Solution of the calces of iron in vitriolic acid, 456. It acts on iron in a much more dilute state than the nitrous, 461. Proportion of copper dissolved by vitriolic acid, 464. Vitriolic air obtained from this solution, 465. Why this metal cannot be acted upon by diluted vitriolic acid, 466. Action of the vitriolic acid on tin, 470. On lead, 474. On silver, 478. On mercury, 485. Zinc, 487. Bismuth, 491. Nickel, 2d 493. Cobalt, 496. Regulus of antimony, 499. Regulus of arsenic, 502. Quantity of phlogiston in vitriolic air, 506. This acid and its combinations particularly treated of, 612, *et seq.* Is never found naturally pure, 612. How rectified, 613. Attracts moisture from the air, 614. Produces cold and heat according to circumstances, 615. Quantity of alkali saturated by it, 616. Its effects on the human body, 617. Difficulty of procuring it by itself, 618. Distillation of it from copperas, 620. Rectification of the acid thus obtained, 622. To procure it from sulphur, 623. Quantity of acid contained in it, 623. Quantity produced from it, 624. Methods of obviating the difficulties in this process, 625. Ought to be made in lead vessels, 627. Of its combination with fixed alkali, 628. With calcareous earth, 635. With argillaceous earth, 637. With magnesia, 690. With metals, 691. With inflammable substances, 712. Bergman's experiments to show that an excess of this acid impedes the crystallization of alum, 681. Procured from the residuum of vitriolic ether, 2d 722. Of its transmutation into the nitrous acid, 720. How to extract the nitrous acid

by its means, 734. Whether the marine acid be the same with it, 783. Experiment seeming to prove the transmutation, 784. Expelled by acid of sugar, 898. Effects of it on salt of amber, 913. Dissolves manganese in conjunction with the acid of tartar, 1012. Or with spirit of wine, 1014. Expelled by the nitrous and marine acids, 1041. Promotes the solubility of salts, 1048. Terra ponderosa usually found united with the vitriolic acid, 1049. Unites with this substance more readily than with alkalis, 1055. Its presence readily discovered by terra ponderosa, 1058. The oil of vitriol usually sold contains gypsum, 1059. Effects of it on arsenic, 1271. Converts the regulus into white arsenic, 1292. On regulus of cobalt, 1300.

Vitriolated tartar: its decomposition by calcareous earth explained, 270. On its decomposition by nitrous acid, 285. Cannot be decomposed by diluted nitrous acid, 287. Decomposed by marine acid, 288. Requisites for the success of this experiment, 289. Cannot be decomposed in a state of solution by this acid, 290. Explanation of its decomposition by solution of silver, 305. Why it is so much heavier than nitre, 416. Of the quantity of ingredients in it, 419. How prepared, 628, 629. Its uses, 631. Decomposed and sulphur procured from it by calcination with charcoal, 716. Its acid expelled by that of phosphorus, 907. And by the arsenical acid, 929.

Volatile alkali less strongly attracted than metallic earths by acids, 303. May be used to remove the excess of acid in aluminous ley, 680. Forms Glauber's sal ammoniac with vitriolic acid, 633. Nitrous ammoniac with the nitrous, 745. Common sal ammoniac with the marine, 795. Vegetable ammoniac with the acetous, 870. A salt forming into elegant crystals with the acid of tartar, 892. Its combination with fluor acid, 851. Glass corroded by this salt, 854. A great quantity of it saturated by acid of sugar, 900. Forms microcosmic salt with the phosphoric acid, 905. Combined with acid of arsenic, 928. In its mild state decomposes calcareous solutions, 1046. Precipitates siliceous earth completely, 1074. Its preparation particularly treated of, 1030, *et seq.* Obtained from various substances, *ib.* Proper way of distilling it, 1031. How purified, 1032. Volatile sal ammoniac, how prepared, 1033. Volatile alkali combined with metals, 1034. With

essential oils and spirit of wine, 1036, 1037. With sulphur, 1038. Volatile tincture of sulphur, 1038. Its use in the preparation of aurum fulminans but lately known, 1106. The cause of its explosion, 1121. Unites with the colouring matter of Prussian blue, 1182. Obtained by distillation from Prussian blue, 1197. May be united with phlogiston and fixed alkali, so as to sustain a great degree of heat, 1202. Effects of it on nickel, 1314. On solution of platina, 1330. Why the volatile sulphureous acid dissolves manganese, 1379. Volatile alkali destroyed by manganese attracting its phlogiston, 1394.

Volcanic countries only afford ores containing alum ready made, 655. *Unguentum citrinum*, how prepared, 772.

Urine, how the microcosmic salt is procured from it, 905. Always contains a calculeous matter, 1457. Why fresh urine reddens lacmus, 1458. Different salts contained in it, 1459. Affords the acid of benzoic, 1532.

WARD'S DROP: Nitrous ammoniac the principal ingredient in it, 746.

Water: Its slowness in melting when congealed, a preventative of inundations, 88. Prodigious force exerted by it in freezing, 106. Remains sometimes fluid though cooled below 32 degrees, 117. Dr Black's experiments on the conversion of water into steam, 121. Its boiling point in vacuo determined by Mr Boyle, 122. And by Mr Robinson of Glasgow, 123. May be made sufficiently hot to melt lead, 131. A great quantity of water yielded by burning spirit of wine, 134. Produced from the deflagration of dephlogisticated and inflammable air, 135. In the reduction of iron by inflammable air, 156. Why it does not unite with nitrous air, 204. Cannot dissolve metallic salts without an excess of acid, 297. Quantity of it in digestive salt, 379. In nitre, 391. In vitriolated tartar, 398. In spirit of nitre, 426. How far it is an object of chemistry, 549. Scheme for filtering large quantities of it, 569. Earthy crust formed on it by fluor acid, 833. See *Crust*. Neutral salt for discovering iron in mineral waters, 1180. Mercury supposed convertible into it, 1235. The mistake discovered by Lewis, 1236. *Waters, mineral*, Mr Woulfe's test for them, 1557.

Watt's experiments on the distillation of water in *vacuo*, 45. On the evaporation of fluids in *vacuo*, 126. His test for acids and alkalis, 1549, *et seq.*

Wedge's improvement of the

thermometer, 104. His stone-ware an improvement in chemical vessels, 597.

Weight of metals increased by calcination, 523, *et seq.*

Wenzel's experiments on fluor acid, 850. Method of preparing crystals of verdigris, 872.

Westrumb's analysis of the residuum of vitriolic ether, 2d 722. His attempt to reduce vinegar nearer to the state of tartar, 1003.

Whey: chemical properties of it, 970. Convertible into vinegar, 979.

White: a beautiful white colour from lead, 703. White drop of Ward, 746. White copper, how prepared, 1157.

Wiegand's experiments on fluor acid, 839. Account of the distillation of nitrous acid by clay, &c. 737. His new chemical nomenclature, 1561.

Wilson's experiments on phosphorus, 1086.

Winch's method of purifying ether, 2d 722. Wines, how purified, 886.

Withering's experiments on terra ponderosa, 1050.

Wolfram. See *Tungsten*.

Wood, preservatives for, 621, 700.

Woodward's receipt for making Prussian blue, 1164.

Woulfe's method of procuring nitrous ether in large quantity, 776. Test for mineral waters, 1557.

YELLOW COLOUR for house-painting, 699.

York, account of the aluminous ore found near that place, 660.

ZAFFRE, a calx of cobalt, described, 1294.

Zinc and iron, the only metals dissolved by vitriolic acid, 337. Of their precipitation by one another, 347. Precipitates nickel, 358. Cannot precipitate cobalt, 361. Forms white vitriol with the vitriolic acid, 707. Combined with the nitrous acid, 767. With the marine acid, 820. Volatilized by it, *ib.* With acid of arsenic, 951. Cannot easily be combined with iron, 1162. Its combination with copper, 1154. The metal particularly treated of, 1240. Deflagrates violently in a strong heat, *ib.* Sublimes into flowers, 1241. Dr Lewis's method of reducing them, 1242. Oil supposed to be obtained from them by Homberg, 1243. The mistake discovered by Neumann, *ib.* Another oil by Mr Hellot, capable of dissolving gold and silver leaf, 1244. Combination of zinc with other metals, 1245. Its combination with gold a proper material for specula, 1246. Its deflagration with other metals, 1247. Cannot be united with sulphur, 1248. Nitre alkali-fied by its flowers, 1249. Unites readily with platina, 1342.

Chemnitz
||
Chenopo-
dium.

CHEMNITZ (Martin), a famous Lutheran divine, the disciple of Melancthon, was born at Britzen in Brandenburg, in 1522. He was employed in several important negotiations by the princes of the same communion; and died in 1589. His principal work is the *Examen of the Council of Trent*, in Latin.

CHEMOSH. See **CHAMOS.**

CHEMOSIS, a disease of the eyes, proceeding from an inflammation; wherein the white of the eye swells above the black, and overtops it to such a degree, that there appears a sort of gap between them. Others define it to be an elevation of the membrane which surrounds the eye, and is called the *white*; being an affection of the eye, like white-flesh.

CHENOPODIUM, Goose-Foot, or *Wild Orach*: A genus of the digynia order, belonging to the pentandria class of plants; and in the natural method ranking under the 12th order, *Holoraceae*. The calyx is pentaphyllous and pentagonal; no corolla; one seed lenticular, superior. There are 18 species, 13 of which are natives of Britain. The most remarkable are the following: 1. The bonus henricus, or common English mercury, found growing naturally in shady lanes in many places in Britain. It has large triangular, arrow-pointed, entire leaves; upright, thick, striated stalks, garnished with triangular leaves, and terminated by close spikes of apetalous yellowish-green flowers in June and July, which are succeeded by ripe seeds in August. 2. The scoparia, belvidere, or annual mock-cypress, which is of a beautiful pyramidal form, resembling a young cypress-tree. 3. The botrys, or oak of Jerusalem. 4. The ambrosoides, or oak of Cappadocia. All these are very easily propagated from seeds; and will thrive best in a rich light earth. Most of the species have an aromatic smell. A species which grows near the Mediterranean is used by the Egyptians in fallads, on account of its saltish aromatic taste. From the same plant kelp is made in other countries.—The first species, or English mercury, was formerly used as spinach; but is now disused, as being greatly inferior to that herb. As an article of the materia medica, it is ranked among the emollient herbs, but rarely made use of in practice. The leaves are applied by the common people for healing slight wounds, cleansing old ulcers, and other like purposes. The roots are given to sheep that have a cough. Goats and sheep are not fond of the herb; cows, horses, and swine, refuse it.—The second species, or belvidere, is a plant much esteemed in China. The following are the properties attributed to it in the Chinese Herbal. After having said that it is about the end of March or beginning of April that the belvidere springs up from the earth; that its suckers or shoots rise to the height of eight or nine inches, in shape of a child's fist half shut; that it afterwards extends itself, and sends forth a number of branches loaded with leaves like those of flax; and that, as it grows, its branches arrange themselves naturally in the form of a beautiful pyramid; it adds, that its leaves, yet tender, abound with juice, and have a very agreeable taste; that it may be eaten as a fallad with vinegar, to which a little ginger has been added; that being prepared like other leguminous plants, and baked with meat, it gives it an agreeable and pleasing flavour: that, when in its full beauty, its

leaves become hard and unfit for the table; but that nourishment is then found in its root, which serves as a resource in times of famine and scarcity. When the belvidere has attained to its natural size, the Chinese separate its principal stalk from the rest, and put it into a lye of ashes, which cleans and softens it, and frees it from all impurities of the bark. After this bath, it is exposed to the sun; and, when dry, it is baked and seasoned. With regard to the root, which has something of a violet-colour, they strip off the skin by filaments, which may be boiled and eaten: but what is particularly sought after, is the root itself; of which, when reduced to powder, they collect only what remains in the bottom of the vessel, and form it into small loaves, that are baked by being held over the steam of boiling water. People of a delicate taste will scarcely be tempted to admit this dish at their tables; but is it not useful to point out to the poor peasants, that, in cases of necessity, they may always have recourse, without danger, to this rustic food? In such cases, they will be indebted to the Chinese for having made the first trial, which, for the most part, is dangerous. The Chinese Herbal cites the example of four mountaineers, who having lived on nothing but the leaves, roots, and stalks, of the belvidere, with which their country abounded, had nevertheless enjoyed perfect health to a very great age.

CHEPELIO, an island in the bay of Panama and province of Darien, in South America, situated about three leagues from the city of Panama, which it supplies with provisions. W. Long. 81. N. Lat. 9.

CHEPSTOW, a market town of Monmouthshire in England, seated on the river Wye near its mouth, in W. Long. 2. 40. N. Lat. 51. 40.

CHEQ, or **CHERIF**, the prince of Mecca, who is, as it were, high priest of the law, and sovereign pontiff of all the Mahometans of whatever sect or country they be. See **CALIPH**.

The grand signior, sophis, moguls, khans of Tartary, &c. send him yearly presents, especially tapestry to cover Mahomet's tomb withal, together with a sumptuous tent for himself, and vast sums of money to provide for all the pilgrims during the 17 days of their devotion.

CHERASCO, a strong and considerable town of Italy, in Piedmont, and capital of a territory of the same name, with a strong citadel belonging to the king of Sardinia, where he retired in 1706, during the siege of Turin. It is seated at the confluence of the rivers Sturia and Tanaro, upon a mountain. E. Long. 7. 55. N. Lat. 44. 35.

CHERBURG, a sea-port town of France, in Normandy, with a harbour and Augustine abbey. It is remarkable for the sea-fight between the English and French fleets in 1692, when the latter were beat, and upwards of twenty of their men of war burnt near Cape la Hogue. The British landed here in August 1758, and took the town, with the ships in the basin, demolished the fortifications, and ruined the other works which had been long carried on for enlarging the harbour and rendering it more safe and convenient. Within these few years it has been attempted again to improve the harbour, and rebuild the works; but after considerable progress had been made, a great part of them suddenly gave way, and the enterprise it

Chepelio

Cherburg.

Cherem is thought will not be again resumed. E. Long. 1. 38. N. Lat. 49. 38.

||
Chermea

CHEREM, among the Jews, is used to signify a species of annihilation. See ANNIHILATION.

The Hebrew word *cherem*, signifies properly to *destroy, exterminate, devote, or anathematise*.

CHEREM is likewise sometimes taken for that which is consecrated, vowed, or offered to the Lord, so that it may no longer be employed in common or profane uses. No devoted thing that a man shall devote unto the Lord, of all that he hath of man and beast, and of the field of his possession, shall be sold or redeemed; every devoted thing is most holy to the Lord: none devoted, which shall be devoted of men, shall be redeemed, but shall surely be put to death. There are some who assert that the persons thus devoted were put to death; whereof Jephtha's daughter is a memorable example. Judges xi. 29. &c.

CHEREM is also used for a kind of excommunication in use among the Jews. See NIDDI.

CHERESOU, or **CHAHZUL**, a town of Turkey in Asia, capital of Curdistan, and the seat of a beglerbeg. E. Long. 45. 15. N. Lat. 36. 0.

CHERILUS, of Samos, a Greek poet, flourished 479 years before Christ. He sung the victory gained by the Athenians over Xerxes, and was rewarded with a piece of gold for every verse. His poem had afterwards the honour of being rehearsed yearly with the works of Homer.

CHERLERIA, in botany: A genus of the trigynia order, belonging to the decandria class of plants; and in the natural method ranking under the 22d order, *Caryophyllea*. The calyx is pentaphyllous; there are five nectaria, bifid, and petal-like; the antheræ alternately barren; the capsule is trilocular and three-valved.

CHERLESQUIOR, in Turkish affairs, denotes a lieutenant general of the grand signior's armies.

Plate
CLXXVIII.

CHERMES, in zoology, a genus of insects belonging to the order of insecta hemiptera. The rostrum is situated on the breast; the feelers are longer than the thorax; the four wings are deflected; the thorax is gibbous; and the feet are of the jumping kind. There are 17 species; and the trivial names are taken from the plants which they frequent, as the *chermes graminis*, or grass-bug; the *chermes ulmi*, or elm-bug, &c. The *chermes ficus*, or fig-tree bug, one of the largest of the genus, is brown above and greenish beneath. The antennæ, likewise brown, are large, hairy, and one third longer than the thorax. The feet are yellowish; the wings large, twice the length of the abdomen. They are placed so as to form together an acute roof. The membrane of which they consist is thin and very transparent; but they have brown veins, strongly marked, especially towards the extremity. The rostrum of this *chermes* is black, and takes its rise from the lower part of the thorax, between the first and second pair of feet. It is an insect to be met with in great numbers upon the fig-tree. The larva has six feet. It is like the insect, when provided with wings. Its form is oblong, and its motion slow. The chrysalis differs from it by two flat buds that spring from the thorax and inclose the wings, afterwards seen in the perfect insect. These chrysalids are frequently met with on plants; and the two

plates of their thorax give them a broad uncouth appearance, and a heavy look. When the little chrysalids are going to be metamorphosed, they remain motionless under some leaves which they fix themselves upon. Their skin then divides upon the head and thorax, and the perfect insect comes forth with his wings, leaving the spoil of his chrysalis open and rent anteriorly upon the leaf. These kind of sloughs are often found beneath the leaves of the fig-tree. The perfect insect is furnished with four wings, large in proportion to its body, veined, and placed in the form of a roof; and with them it flies. It has, moreover, the faculty of leaping pretty briskly, by means of its hinder-legs, which play like a spring. When it is attempted to catch the *chermes*, it makes its escape rather by leaping than flying. Some of those insects have a manœuvre worthy of notice. Several species are provided at the extremity of their body with a small sharp-pointed implement, but which lies concealed, and that they draw out in order to deposit their eggs, by making a puncture in the plant that suits them. By this method the fir-tree *chermes* produces that enormous scaly protuberance that is to be found at the summit of the branches of that tree, and which is formed by the extravasation of the juices occasioned by the punctures. The young larvæ shelter themselves in cells contained in the tumor. The white down, under which the larva of the pine-*chermes* is found, seems to be produced much in the same manner. That of the box-tree *chermes* produces no tubercula like those; but its punctures make the leaves of that tree bend and grow hollow in the shape of a cap, which by the union of those infected leaves produces at the extremity of the branches a kind of knobs, in which the larvæ of that insect find shelter. The box-*chermes*, as well as some others, has yet another peculiarity, which is, that the larva and its chrysalis eject at the anus a white sweet-tasted matter, that softens under the touch, and is not unlike manna. This substance is found in small white grains within the balls formed by the box-leaves, and a string of the same matter is often seen depending from the anus of the insect.

CHERMES Mineral. See KERMES.

CHERRY-ISLAND, an island in the northern ocean, lying between Norway and Greenland, in E. Long. 20. 5. N. Lat. 75. 0.

CHERRY-Tree, in botany. See PRUNUS.

CHERSO, an island in the gulph of Venice, with a town of the same name near Croatia, belonging to the Venetians. The air is good, but the soil stony; however, it abounds in wine, cattle, oil, and excellent honey. E. Long. 15. 5. N. Lat. 45. 8.

CHERSONESUS, among modern geographers, the same with a peninsula; or a continent almost encompassed round with the sea, only joining to the main land by a narrow neck or isthmus. The word is Greek, *χερσονησος*; of *χερσος*, land, and *νησος*, island; which signifies the same. In ancient geography, it was applied to several peninsulas; as the *Chersonesus Aurea*, *Cimbrica*, *Taurica*, and *Thracia*, now thought to be Malacca, Jutland, Crim Tartary, and Romania.

CHERT, **PETROSILEX**, *Lapis Corneus*, the *Hornstein* of the Germans; a species of stone classed by Cronstedt among the siliceous earths. It is of a coar-

Chermes

||
Chert.

Chert
||
Cherub.

ser texture than the common flint, as well as softer; for which reasons it is not capable of such a fine polish. It is semitransparent at the edges, or when broken into very thin pieces. It is found of different colours, viz. white, whitish-yellow, flesh-coloured, and greenish. According to Mr Kirwan, it runs in veins through rocks, from whence its name is derived; its specific gravity being from 2590 to 2700. In the fire it whitens and decrepitates like flint, but is generally fusible *per se*. Mineral alkali does not totally dissolve it in the dry way, but borax and microcosmic salt do so without effervescence. Its appearance is duller and less transparent than common flint. The reddish petrosilex, used in the count de Lauragais's porcelain manufactory, and there called *feld-spat*, contained 72 *per cent.* of flint, 22 of argill, and 6 of calcareous earth.

Cronstedt observes that there are not as yet any certain characters known by which the cherts and jaspers may be distinguished from one another, though they can easily be so by sight; the cherts appearing of a fine sparkling texture when broken; but the jasper being grained, dull, and opaque, and having the appearance of a dry clay. The chert is also found forming larger or smaller veins, or in nodules like kernels in rocks; whereas the jasper, on the contrary, sometimes constitutes the principal part of the highest and most extended mountains. The chert is likewise found plentifully in the neighbourhood of scaly limestone, as flints are in the strata of chalk.

The connection between these bodies is not yet discovered; but it is impossible to establish any essential difference between them, from the circumstance of flints and agates being generally found in single, loose, and irregular nodules, and hardly in rocks like the chert: for near Constantinople the agate stone runs in a vein across the rock, of the same hardness, and as fine and transparent, as those agates found in round nodules at Deux Ponts.

CHERTZEY, a market town of Surrey in England, about seven miles west from Kingston upon Thames. W. Long. 30'. N. Lat. 51. 25.

CHERUB, (plural, CHERUBIM); a celestial spirit, which in the hierarchy is placed next to the seraphim. See HIERARCHY.

The term *cherub*, in Hebrew, is sometimes taken for a calf or ox. Ezekiel sets down the face of a cherub as synonymous to the face of an ox. The word *cherub*, in Syriac and Chaldee, signifies to *till* or *plow*, which is the proper work of oxen. Cherub also signifies *strong* and *powerful*. Grotius says, that the Cherubim were figures much like that of a calf. Bochart thinks likewise, that the cherubim were more like to the figure of an ox than to any thing besides; and Spencer is of the same opinion. Lastly, St John, in the Revelations, calls cherubim *beasts*. Josephus says the cherubim were extraordinary creatures, of a figure unknown to mankind. Clemens of Alexandria believes, that the Egyptians imitated the cherubim of the Hebrews in the representations of their sphinxes and their hieroglyphical animals. All the several descriptions which the scripture gives us of cherubim differ from one another; but all agree in representing them as a figure composed of various creatures, as a man, an ox, an eagle, and a lion. Such were the cherubim described by Ezekiel. Those which Isaiah

saw, and are called *seraphim* by him, had the figure of a man with six wings; with two whereof they covered their faces, with two more they covered their feet, and with the two others they flew. Those which Solomon placed in the temple of Jerusalem are supposed to have been nearly of the same form. Those which St John describes in the Revelations were all eyes before and behind, and had each six wings. The first was in the form of a lion, the second in that of a calf, the third of a man, and the fourth of an eagle. The figure of the cherubim was not always uniform, since they are differently described in the shapes of men, eagles, oxen, lions, and in a composition of all these figures put together. Moses likewise calls these symbolical or hieroglyphical representations, which were embroidered on the veils of the tabernacle, *cherubim* of costly work. Such were the symbolical figures which the Egyptians placed at the gates of their temples and the images of the generality of their gods, which were commonly nothing but statues composed of men and animals.

CHERVIL, in botany. See CHÆROPHYLLUM.

CHESAPEAKE, in America, one of the largest bays in the known world. Its entrance is between Cape Charles and Cape Henry in Virginia, 12 miles wide; and it extends 270 miles to the northward, dividing Virginia and Maryland. Through this extent it is from 7 to 18 miles broad, and generally about 9 fathoms deep; affording many commodious harbours, and a safe and easy navigation. It receives the waters of the Susquehannah, Patomak, Rappahannock, York, and James rivers, which are all large and navigable.

CHESELDEN (William), an eminent anatomist and surgeon, was born at Burrow on the Hill, in the county of Leicester, descended from an ancient family in the county of Rutland, whose arms and pedigree are in Wright's "History of Rutland." He received the rudiments of his professional skill at Leicester; and married Deborah Knight, a citizen's daughter, by whom he had one daughter, Williamina Deborah. In 1713 he published his *Anatomy of the Human Body*, one volume 8vo; and in 1723, *A Treatise on the High Operation for the Stone*. He was one of the earliest of his profession who contributed by his writings to raise it to its present eminence. In the beginning of 1736, he was thus honourably mentioned by Mr Pope: "As soon as I had sent my last letter, I received a most kind one from you, expressing great pain for my late illness at Mr Cheselden's. I conclude you was eased of that friendly apprehension in a few days after you had dispatched yours, for mine must have reached you then. I wondered a little at your quære, Who Cheselden was? It shows that the truest merit does not travel so far any way as on the wings of poetry: he is the most noted and most deserving man in the whole profession of chirurgery; and has saved the lives of thousands by his manner of cutting for the stone." He appears to have been on terms of the most intimate friendship with Mr Pope, who frequently, in his Letters to Mr Richardson, talks of dining with Mr Cheselden, who then lived in or near Queen Square. In February 1737, Mr Cheselden was appointed surgeon to Chelsea hospital. As a governor of the Foundling Hospital

fpital, he fent a benefaction of 50 l. to that charity, May 7. 1751, inclofed in a paper with the following lines :

'Tis what the happy to th' unhappy owe ;
For what man gives, the gods by him beftow. POPE.

He died at Bath, April 11. 1752, of a diforder arifing from drinking ale after eating hot buns. Finding himfelf uneasy, he fent for a phyfician, who advifed vomiting immediately ; and if the advice had been taken, it was thought his life might have been faved. By his direction, he was buried at Chelfea.

CHESHIRE, a maritime county of England, bounded by Lancashire on the north ; Shropshire and part of Flintshire, on the fouth ; Derbyshire and Staffordshire, on the east and fouth-east ; and Denbighshire and part of Flintshire on the west and north-west. It extends in length about 44 miles, in breadth 25 ; and is fupposed to contain 125,000 inhabitants. Both the air and foil in general are good. In many places of the country are peat-moffes, in which are often found trunks of fir-trees, fometimes feveral feet under ground, that are ufed by the inhabitants both for fuel and candles. Here alfo are many lakes and pools well ftored with fifh ; befides the rivers Merfee, Weaver, and Dee, which laft falls into a creek of the Irish fea near Chefter. This county alfo abounds with wood : but what it is chiefly remarkable for, is its cheefe, which has a peculiar flavour, generally thought not to be inferior to any in Europe ; (fee CHEESE). The principal towns are, Chefter the capital, Cholmondely, Namptwitch, &c.

William the Conqueror erected this county into a palatinate, or county-palatine, in favour of his nephew Hugh Lupus, to whom he granted the fame fovereignty and jurifdiction in it that he himfelf had in the reft of the ifland. By virtue of this grant, the town of Chefter enjoyed fovereign jurifdiction within its own precincts ; and that in fo high a degree, that the earls held parliaments, confifting of their barons and tenants, which were not bound by the acts of the Englifh parliament : but this exorbitant power of the palatinates was at laft reduced by Henry VIII. ; however, all cafes and crimes, except thofe of error, foreign-plea, foreign-voucher, and high-treafon, are ftill heard and determined within the fhire. The earls were anciently fuperiors of the whole county, and all the landholders were mediately or immediately their vaffals, and under the like fovereign allegiance to them as they were to the kings of England ; but the earldom was united to the crown by Edward III. fince which time, the eldeft fons of kings of England have always been earls of Chefter, as well as princes of Wales. Chefhire fends four members to parliament ; two for the county, and two for the capital.

CHESNE (Andrew du), ftyled the father of French hiftory, was born in 1584. He wrote, 1. A hiftory of the popes. 2. An hiftory of England. 3. An inquiry into the antiquities of the towns of France. 4. An hiftory of the cardinals. 5. A bibliotheca of the authors who have written the hiftory and topography of France, &c. He was crufted to death by a cart, in going from Paris to his country-houfe at Verriere, in 1640.

CHESNUT-TREE. See FAGUS.

Chefe.

CHESS, an ingenious game performed with different pieces of wood, on a board divided into 64 fquares or houfes ; in which chance has fo fmall a fhare, that it may be doubted whether a perfon ever loft a game but by his own fault.

Each gamefter has eight dignified pieces, viz. a king, a queen, two bifhops, two knights, and two rooks, alfo eight pawns : all which, for diftinction's fake, are painted of two different colours, as white and black.

As to their difpofition on the board, the white king is to be placed on the fourth black houfe from the corner of the board, in the firft and lower rank ; and the black king is to be placed on the fourth white houfe on the oppofite, or adverfary's, end of the board. The queens are to be placed next to the kings, on houfes of their own colour. Next to the king and queen, on each hand, place the two bifhops ; next to them, the two knights ; and laft of all, on the corners of the board, the two rooks. As to the pawns, they are placed, without diftinction, on the fecond rank of the houfe, one before each of the dignified pieces.

Having thus difpofed the men, the onfet is commonly begun by the pawns, which march ftraight forward in their own file, one houfe at a time, except the firft move, when it can advance two houfes, but never moves backwards : the manner of their taking the adverfary's men is fide-ways, in the next houfe forwards ; where having captivated the enemy, they move forward as before. The rook goes forward or crofs-ways through the whole file, and back again. The knight fhips backward and forward to the next houfe, fave one, of a different colour, with a fidling march, or a flope, and thus kills his enemies that fall in his way, or guards his friends that may be expofed on that fide. The bifhop walks always in the fame colour of the field that he is placed in at firft, forward and backward, aflope, or diagonally, as far as he lifts. The queen's walk is more univerfal, as ſhe takes all the fteps of the before mentioned pieces, excepting that of the knight ; and as to the king's motion, it is one houfe at a time, and that, either forward, backward, floping, or fide-ways.

As to the value of the different pieces, next to the king is the queen, after her the rooks, then the bifhops, and laft of the dignified pieces comes the knight. The difference of the worth of pawns, is not fo great as that of noblemen ; only, it muft be obferved, that the king's bifhop's pawn is the beft in the field, and therefore the ſkilful gamefter will be careful of him. It ought alfo to be obferved, that whereas any man may be taken, when he falls within the reach of any of the adverfary's pieces, it is otherwife with the king, who, in fuch a cafe, is only to be faluted with the word *check*, warning him of his danger, out of which it is abfolutely neceffary that he move ; and, if it fo happen that he cannot move without expofing himfelf to the like inconveniency, it is check-mate, and the game is loft. The rules of the game are,

1. In order to begin the game, the pawns muft be moved before the pieces, and afterwards the pieces muft be brought out to fupport them. The king's, queen's, and bifhop's pawns, ſhould be moved firft, that the game may be well opened ; the pieces muft not be played out early in the game, becaufe the player may thereby lofe.

Chess.

Chess.

lose his moves : but above all, the game should be well arranged before the queen is played out. Useless checks should also be avoided, unless some advantage is to be gained by them, because the move may be lost, if the adversary can either take or drive the piece away.

2. If the game is crowded, the player will meet with obstructions in moving his pieces; for which reason he should exchange pieces or pawns, and castle (A) his king as soon as it is convenient, endeavouring at the same time to crowd the adversary's game, which may be done by attacking his pieces with the pawns, if the adversary should move his pieces out too soon.

3. The men should be so guarded by one another, that if a man should be lost, the player may have it in his power to take one of the adversary's in return; and if he can take a superior piece in lieu of that which he lost, it would be an advantage, and distress the adversary.

4. The adversary's king should never be attacked without a force sufficient; and if the player's king should be attacked without having it in his power to attack the adversary's, he should offer to make an exchange of pieces, which may cause the adversary to lose a move.

5. The board should be looked over with attention, and the men reconnoitred, so as to be aware of any stroke that the adversary might attempt in consequence of his last move. If, by counting as many moves forward as possible, the player has a prospect of success, he should not fail doing it, and even sacrifice a piece or two to accomplish his end.

6. No man should be played till the board is thoroughly examined, that the player might defend himself against any move the adversary has in view; neither should any attack be made till the consequences of the adversary's next move are considered; and when an attack may with safety be made, it should be pursued without catching at any bait that might be thrown out in order for the adversary to gain a move, and thereby cause the design to miscarry.

7. The queen should never stand in such a manner before the king, that the adversary, by bringing a rook or bishop, could check the king if she were not there; as it might be the loss of the queen.

8. The adversary's knight should never be suffered to check the king and queen, or king and rook, or queen and rook, or the two rooks at the same time; especially if the knight is properly guarded: because, in the two first cases, the king being forced to go out of check, the queen or the rook must be lost; and in the two last cases a rook must be lost at least for a worse piece.

9. The player should take care that no guarded pawn of the adversary's fork two of his pieces.

10. As soon as the kings have castled on different sides of the board, the pawns on that side of the board should be advanced upon the adversary's king, and the pieces, especially the queen and rook, should be brought

N^o 77.

to support them; and the three pawns belonging to the king that is castled must not be moved.

11. The more moves a player can have as it were in ambuscade, the better; that is to say, the queen, bishop, or rook, is to be placed behind a pawn or a piece, in such a position as that upon playing that pawn or piece a check is discovered upon the adversary's king, by which means a piece or some advantage is often gained.

12. An inferior piece should never be guarded with a superior, when a pawn would answer the same purpose; for this reason, the superior piece may remain out of play; neither should a pawn be guarded with a piece when a pawn would do as well.

13. A well supported pawn that is passed often costs the adversary a piece; and when a pawn or any other advantage is gained without endangering the loss of the move, the player should make as frequent exchanges of pieces as he can. The advantage of a passed pawn is this: for example, if the player and his adversary have each three pawns upon the board, and no piece, and the player has one of his pawns on one side of the board, and the other two on the other side, and the adversary's three pawns are opposite to the player's two pawns, he should march with his king as soon as he can, and take the adversary's pawns: If the adversary goes with his king to support them, the player should go on to queen with his single pawns; and then if the adversary goes to hinder him, he should take the adversary's pawns, and move the others to queen (B).

14. When the game is near finished, each party having only three or four pawns on each side of the board, the kings must endeavour to gain the move in order to win the game. For instance, when the player brings his king opposite to the adversary's with only one square between, he will gain the move.

15. If the adversary has his king and one pawn on the board, and the player has only his king, he cannot lose the game, provided he brings his king opposite to the adversary's, when the adversary is directly before or on one side of his pawn, and there is only one square between the kings.

16. If the adversary has a bishop and one pawn on the rook's line, and this bishop is not of the colour that commands the corner square the pawn is going to, and the player has only his king, if he can get into that corner, he cannot lose; but, on the contrary, may win by a stale (C).

17. If the player has greatly the disadvantage of the game, having only his queen left in play, and his king happens to be in a position to win, as above mentioned, he should keep giving check to the adversary's king, always taking care not to check him where he can interpose any of his pieces that make the stale; by so doing he will at last force the adversary to take his queen, and then he will win the game by being in a stale-mate.

18. The

(A) *Castle his king*, is to cover the king with a castle; which is done by a certain move which each player has a right to whenever he thinks proper.

(B) *To queen*, is to make a queen; that is, to move a pawn into the adversary's back row, which is the rule at this game when the original one is lost.

(C) When the king is blocked up so as to have no move at all.

Chefs.

18. The player should never cover a check with a piece that a pawn pushed upon it may take, for fear of getting only the pawn in exchange for the piece.

19. A player should never crowd his adversary up with pieces, for fear of giving a stale-mate inadvertently, but always should leave room for his king to move.

By way of corroborating what has been already said with respect to this game, it is necessary to warn a player against playing a timid game. He should never be too much afraid of losing a rook for an inferior piece; because although a rook is a better piece than any other except the queen, it seldom comes into play to be of any great use till at the end of the game; for which reason it is often better to have an inferior piece in play, than a superior one to stand still, or moving to no great purpose. If a piece is moved, and is immediately drove away by a pawn, it may be reckoned a bad move, because the adversary gains a double advantage over the player, in advancing at the same time the other is made to retire; although the first move may not seem of consequence between equal players, yet a move or two more lost after the first makes the game scarcely to be recovered.

There never wants for variety at this game, provided the pieces have been brought out regular; but if otherwise, it often happens that a player has scarce any thing to play.

Many indifferent players think nothing of the pawns, whereas three pawns together are strong; but four, which constitute a square, with the assistance of other pieces, well managed, make an invincible strength, and in all probability may produce a queen when very much wanted. It is true, that two pawns with a space between are no better than one; and if there should be three over each other in a line, the game cannot be in a worse way. This shows that the pawns are of great consequence, provided they are kept close together.

Some middling players are very apt to risk losing the game in order to recover a piece; this is a mistake; for it is much better to give up a piece and attack the enemy in another quarter; by so doing, the player has a chance of snatching a pawn or two from, or gaining some advantage over, the adversary, whilst his attention is taken up in pursuing this piece.

If the queen and another piece are attacked at the same time, and that by removing the queen the piece must be lost; provided two pieces can be gained in exchange for the queen, the queen should be given up, it being the difference of three pieces, and consequently more than the value of the queen. By losing the queen, the game is not thrown into that disorder which it would otherwise have been: in this case it would be judicious to give the queen for even a piece, or a pawn or two; it being well known among good players, that he who begins the attack, and cannot maintain it, being obliged to retire, generally loses the game.

A player should never be fond of changing without reason, because the adversary, if he is a good player, will ruin his situation, and gain a considerable advantage over him. But rather than lose a move, when a player is stronger than the adversary, it is good play to change, for he thereby increases his strength.

When the game is almost drawn to a conclusion, the player should recollect that his king is a capital

VOL. IV. Part II.

piece, and consequently should keep him in motion; by so doing he generally gets the move, and often the game.

As the queen, rook, and bishop, operate at a distance, it is not always necessary in the attack to have them near the adversary's king.

If a man can be taken with different pieces, the player should take his time, and consider which of those pieces is the best to take it with.

If a piece can be taken almost at any time, the player should not be in a hurry about it, but try to make a good move elsewhere before he takes it.

A player should be cautious how he takes his adversary's pawn with his king, as it often happens to be a safe-guard to it.

After all that has been said, it is still necessary for us to advise those who would play well at this game, to be very cool and attentive to the matter in question; for it is impossible that any person in the universe can be capable of playing at chefs if their thoughts are employed elsewhere. The laws at this game are,

1. If a player touches his man, he must play it, and if he quits it, he cannot recal it.

2. If by mistake or otherwise a false move is played, and the adversary takes no notice of it till he hath played his next move, it cannot be recalled by either of the parties.

3. If a player misplaces the men, and he plays two moves, it is at the option of the adversary to permit him to begin the game or not.

4. If the adversary plays or discovers a check to a player's king, and gives no notice of it, the player may let him stand still till he does.

5. After the king is moved, a player cannot castle.

Sarasin has an express treatise on the different opinions of the origin of the Latin *schacchi*, whence the French *echecs*, and our *chefs*, is formed. Menage is also very full on the same head. Leunclavius takes it to come from *Ufcoches*, famous Turkish robbers: P. Sirmond, from the German *seachbe*, "theft;" and that from *calculus*. He takes *chefs* to be the same with the *ludus latruncularum* of the Romans, but mistakenly. This opinion is countenanced by Vossius and Salmasius, who derive the word from *calculus*, as used for *latrunculus*. G. Tolofanus derives it from the Hebrew, *seach*, *vallavit et mat mortuus*; whence *check* and *check-mate*. Fabricius says, a celebrated Persian astronomer, one Schatrenscha, invented the game of *chefs*; and gave it his own name, which it still bears in that country. Nicod derives it from *schecque*, or *seque*, a Moorish word for lord, king, and prince. Bochart adds, that *seach* is originally Persian; and that *seach-mat*, in that language, signifies the king is dead.—The opinion of Nicod and Bochart, which is likewise that of Scriverius, appears the most probable.

Mr Twiss mentions a small treatise on chefs, written, as he supposes, about 400 years ago; at the end of which is a representation of a round chefs-board, with directions for placing the men upon it. In this the knight can cover the 64 squares on the board at as many moves. The board is divided into these 64 parts by four concentric circles, having an empty space in the middle; and each of these is divided into 16 parts. Number 1 is placed in the outermost circle; number 2 in the third circle counting inwards, in the division to

4 M

the

Chefs.

Chefs.

the right hand of the former; number 3 is placed in the outermost circle, in the division to the right hand of 2; 4 in the third circle counting inwards to the right hand of three; and thus alternately from the first to the third, and from the third to the first circle, till the round is completed by 16 on the third circle to the left hand of 1. Number 17 is then placed on the division of the innermost circle to the right hand of 1; 18 on the second circle counting inwards, to the right hand of 17; and thus alternately from the fourth to the second, and from the second to the fourth circles, until the round is completed by 32, directly below number 1. Number 33 then is placed on the third circle directly to the right hand of number 2; 34 on the fourth circle, to the right hand of 4; and thus alternately between the third and fourth circles, until the round is again completed by 48 on the fourth circle, directly below number 33. The numbers are now placed in a retrograde fashion; 50 on the outer circle in that division immediately to the right hand of 1; 51 on the third circle, to the left hand of 2, and directly below number 32; 52 is then placed on the outer circle, immediately on the left hand of 1; 53 on the third circle directly to the left hand of 16; and thus alternately on the first and third circles, until the last round is completed by 64 between the numbers 3 and 5. On this round chess-board, supposing the black king to be placed in number 48 on the fourth circle, the queen stands on number 17 at his left hand; the bishops in 33 and 2; the knights 18 and 47; the castles in 3 and 50; the pawns on 19, 4, 49, 64, and 46, 51, 32, 1. The white king will then stand in 25, opposite to the black queen; the white queen in 40 opposite to the black king, and so on. In playing on a board of this kind, it will be found, that the power of the castle is double to that in the common game, and that of the bishop only one half; the former having 16 squares to range in, and the last only four. The king can castle only one way; and it is very difficult to bring the game to a conclusion.

With regard to the origin of the game at chess, we are much in the dark. Though it came to us from the Saracens, it is by no means probable that they were the original inventors of it. According to some, it was invented by the celebrated Grecian hero Diomedes. Others say, that two Grecian brothers, Ledo and Tyrrheno, were the inventors; and that being much pressed with hunger, they sought to alleviate the pain by this amusement. It is certain, however, that it is a game of very ancient standing, and in former ages has been very fashionable in every part of Europe; though in this country it is not now very common, probably on account of the intense application of thought required to play at it. It has long been a favourite of the Icelanders and other northern people. There is little difference between their game and ours.

The game of chess has been generally practised by the greatest warriors and generals; and some have even supposed that it was necessary for a military man to be well skilled in this game. It is a game which has something in it peculiarly interesting. We read that Tamerlane was a great chess-player, and was engaged in a game during the very time of the decisive battle with Bajazet the Turkish emperor, who was defeated and taken pri-

soner. It is also related of Al Amin the khalif of Bagdad, that he was engaged at chess with his freedman Kuthar at the time when Al Mamun's forces were carrying on the siege of that city with so much vigour that it was on the point of being carried by assault. Dr Hyde quotes an Arabic history of the Saracens, in which the khalif is said to have cried out when warned of his danger, Let me alone, for I see checkmate against Kuthar! We are told that Charles I. was at chess when news were brought of the final intention of the Scots to sell him to the English; but so little was he discomposed by this alarming intelligence, that he continued his game with the utmost composure; so that no person could have known that the letter he received had given him information of any thing remarkable. King John was playing at chess when the deputies from Rouen came to acquaint him that their city was besieged by Philip Augustus; but he would not hear them until he had finished his game.

The following remarkable anecdote we have from Dr Robertson in his History of Charles V. John Frederic, elector of Saxony, having been taken prisoner by Charles, was condemned to death. The decree was intimated to him while at chess with Ernest of Brunswic, his fellow-prisoner. After a short pause, and making some reflections on the irregularity and injustice of the emperor's proceedings, he turned to his antagonist, whom he challenged to finish the game. He played with his usual ingenuity and attention; and having beat Ernest, expressed all the satisfaction that is commonly felt on gaining such victories. He was not, however, put to death, but set at liberty after five years confinement.

In the Chronicle of the Moorish kings of Granada we find it related, that in 1396, Mehemed Balba seized upon the crown in prejudice of his elder brother, and passed his life in one continual round of disasters. His wars with Castile were invariably unsuccessful; and his death was occasioned by a poisoned vest. Finding his case desperate, he dispatched an officer to the fort of Salobrena to put his brother Juzaf to death, lest that prince's adherents should form any obstacle to his son's succession. The alcaide found the prince playing at chess with an *alfaqui* or priest. Juzaf begged hard for two hours respite, which was denied him; at last with great reluctance the officer permitted him to finish the game; but before it was finished a messenger arrived with the news of the death of Mehemed, and the unanimous election of Juzaf to the crown.

We have a curious anecdote of Ferrand count of Flanders; who having been accustomed to amuse himself at chess with his wife, and being constantly beaten by her, a mutual hatred took place; which came to such an height, that when the count was taken prisoner at the battle of Bovines, she suffered him to remain a long time in prison though she could easily have procured his release.

The game of chess has undergone considerable variations since it was first invented. We have it on good authority, that among the eastern nations, the piece now called the *queen* was formerly called the *vizir* or king's minister, and that the powers of the queen herself were but very small. The chess-boards used by Tamerlane were larger, and contained many more squares,

Chefs.

Chefs,
Cheft.

squares, than those at present in use. Carrera invented two new pieces to be added to the eight commonly in use. One of these, which he calls *Campione*, is placed between the king's knight and castle; the other, named *Centaur*, between the queen's knight and castle, has the move of the bishop and knight united. This invention, however, did not survive its author. In another of this kind, the two additional pieces are called the *centurion* and *decurion*; the former, situated between the king and his bishop, in its move the same with that of the queen, but only for two squares; the latter moves as the bishop, but only one square at a time. This, like the former, died with its inventor. The chess-board of Tamerlane was a parallelogram, having eleven squares one way and twelve the other. In the Memoirs of the late Marshal Keith, we find it related, that he invented an amusement something similar to that of chess, with which the king of Prussia was highly entertained. Several thousand small statues were cast by a founder; and these were ranged opposite to each other as if they had been drawn up in an army; making the different movements with them as in real service in the field.

A very complicated kind of game at chess was invented by the late duke of Rutland. At this the board has 14 squares in breadth and 10 in height, which make in all 140 houses; and there are 14 pawns on each side, which may move either one, two, or three squares the first time. The other pieces were the king, queen, two bishops, two knights, a crowned castle uniting the move of the king and castle, and a common castle. On the other side of the king was a *concubine*, whose move united that of the castle and knight, two bishops, a single knight, a crowned castle, and a common one. In this game the pawns are of very little use; and by the extent of the board, the knights lose much of their value, which consequently renders the game more defective and less interesting than the common one.

There is an amusing variety at the game of chess, in which the king with eight pawns engages the whole set, by being allowed to make two moves for every one of his adversary. In this he is almost certain of coming off victorious; as he can make his first move into check, and the second out of it. Thus he can take the queen when she stands immediately before her king, and then retreat; for he cannot remain in check. He cannot be check-mated unless his adversary has preserved his queen and both castles.

CHESS-Trees, *taquets d'ancre*; two pieces of wood bolted perpendicularly, one on the starboard, and another on the larboard, side of the ship. They are used to confine the *clue*, or lower corners of the main-sail; for which purpose there is a hole in the upper part, through which the rope passes that usually extends the clue of the sail to windward. See TACK.

The chess-trees are commonly placed as far before the main-mast as the length of the main-beam.

CHEST, in commerce, a kind of measure, containing an uncertain quantity of several commodities.

A chest of sugar, *v. g.* contains from ten to fifteen hundred weight; a chest of glass, from two hundred to three hundred feet; of Castile soap, from two and an half to three hundred weight; of indigo, from one

and an half to two hundred weight, five score to the hundred.

CHEST, or *Thorax*. See ANATOMY, Part IV.

CHESTER, commonly called *West-Chester*, to distinguish it from many other Chesters in the kingdom; the capital of Cheshire, in England. It is a very ancient city, supposed to have been founded by the Romans; and plainly appears to have been a Roman station by the many antiquities which have been and are still discovered in and about the town. It was among the last places the Romans quitted; and here the Britons maintained their liberty long after the Saxons had got possession of the rest of their country. At present it is a large well-built wealthy city, and carries on a considerable trade. Mr Pennant calls it *a city without parallel*, on account of the singular structure of the four principal streets. They are as if excavated out of the earth, and sunk many feet beneath the surface: the carriages drive far beneath the level of the kitchens on a line with ranges of shops. The houses are mostly of wood, with galleries, piazzas, and covered walls before them; by which not only the shops, but those who are walking about the town, are so hid, that one would imagine there were scarce any inhabitants in it, though it is very populous. But though by this contrivance such as walk the streets are screened from rain, &c. yet the shops are thereby rendered dark and inconvenient. The back courts of all the houses are on a level with the ground; but to go into any of the four principal streets, it is necessary to descend a flight of several steps.

Chester is a bishop's see. It was anciently part of the diocese of Litchfield; one of whose bishops removing the seat of his see hither in the year 1075, occasioned his successors to be frequently styled *bishops of Chester*. But it was not erected into a distinct bishoprick until the general dissolution of monasteries, when king Henry VIII. in the year 1541, raised it to this dignity, and allotted the church of the abbey of St Werburg for the cathedral, styling it the *cathedral church of Christ and the blessed Virgin*; adding the bishoprick to the province of Canterbury: but soon after he disjoined it from Canterbury, and added it to the province of York. When this abbey was dissolved, its revenues were valued at L. 1003 : 5 : 11. This diocese contains the entire counties of Chester and Lancaster, part of the counties of Westmoreland, Cumberland, and Yorkshire, two chapelries in Denbyshire, and five parishes in Flintshire; amounting in all to 256 parishes, of which 101 are impropriations. This bishoprick is valued in the king's books at L. 420 : 1 : 8, and is computed to be worth annually L. 2700; the clergy's tenth amounting to L. 435 : 12 : 0. To this cathedral belong a dean, two archdeacons, a chancellor, a treasurer, six prebendaries, and other inferior officers and servants. W. Long. 3. o. N. Lat. 53. 12.

CHESTER-le-Street, the *Cuneacestre* of the Saxons; a small thoroughfare town between Newcastle and Durham, with a good church and fine spire. In the Saxon times this place was greatly respected on account of the relics of St Cuthbert, deposited here by bishop Eardulf, for fear of the Danes, who at that time (about 884) ravaged the country. His shrine

Chest,
Chester.

New-Chef-
ter
||
Cheviot. became afterwards an object of great devotion. King Athelston, on his expedition to Scotland, paid it a visit, to obtain, by intercession of the saint, success on his arms; bestowed a multitude of gifts on the church; and directed, in case he died in his enterprize, that his body should be interred there. At the same time that this place was honoured with the remains of St Cuthbert, the bishoprick of Lindesfarn was removed here, and endowed with all the lands between the Tyne and the Were, the present county of Durham. It was styled *St Cuthbert's patrimony*. The inhabitants had great privileges, and always thought themselves exempt from all military duty, except that of defending the body of their saint. Chester-le-Street may be considered as the parent of the see of Durham; for when the relics were removed there, the see in 995 followed them. Tanner says, that probably a chapter of monks, or rather secular canons, attended the body at this place from its first arrival: but bishop Beke, in 1286, in honour of the saint, made the church collegiate, and established here a dean and suitable ecclesiastics; and, among other privileges, gives the dean a right of fishing on the Were, and the tythe of fish.

New CHESTER, a town of Pennsylvania in America, and capital of a county of that name. It is seated on the Delawar; and has a fine capacious harbour, admitting vessels of any burden. W. Long. 74. 7. N. Lat. 40. 15.

CHESTERFIELD, a market town of Derbyshire in England, pleasantly situated on a hill between two small rivers. It has the title of an earldom; and a considerable market for corn, lead, and other country commodities. The houses are, for the most part, built of rough stone, and covered with slate. W. Long. 1. 25. N. Lat. 53. 20.

CHESTERFIELD (Earl of). See STANHOPE.

CHEVAL *de Frise*, a large piece of timber pierced, and traversed with wooden spikes, armed or pointed with iron, five or six feet long. See Plate CXXXVI.

The term is French, and properly signifies a *Friesland horse*; as having been first invented in that country.—It is also called a *Turnpike* or *Turniquet*.

Its use is to defend a passage, stop a breach, or make a retrenchment to stop the cavalry. It is sometimes also mounted on wheels, with artificial fires, to roll down in an assault. Errard observes, that the prince of Orange used to inclose his camp with *Chevaux de Frise*, placing them one over another.

CHEVALER, in the manege, is said of a horse, when, in passing upon a walk or trot, his off fore-leg crosses or overlaps the near fore-leg every second motion.

CHEVALIER, a French term, ordinarily signifying a KNIGHT. The word is formed of the French, *cheval*, "horse;" and the barbarous Latin *cavallus*.

It is used, in heraldry, to signify any *cavalier*, or horseman armed at all points; by the Romans called *cataphractus eques*: now out of use, and only to be seen in coat-armour.

CHEVAUX *de Frise*. See CHEVAL *de Frise*.

CHEVIN, a name used in some parts of England for the CHUB.

CHEVIOT (or TIVLOT) HILLS, run from north to south through Cumberland; and were formerly the

borders or boundaries between England and Scotland, Chevisance- where many a bloody battle has been fought between the two nations; one of which is recorded in the ballad of Chevy-chase. These hills are the first land discovered by sailors in coming from the east into Scotland.

CHEVISANCE, in law, denotes an agreement or composition, as an end or order set down between a creditor and his debtor, &c. In the statutes, this word is most commonly used for an unlawful bargain or contract.

CHEVREAU (Urban), a learned writer, born at Lundun in 1613. He distinguished himself in his youth by his knowledge of the belles lettres; and became secretary of state to queen Christina of Sweden. Several German princes invited him to their courts; and Charles-Lewis, the elector palatine, retained him under the title of counsellor. After the death of that prince, he returned to France, and became preceptor to the duke of Maine. At length retiring to Lundun, he died there in 1701, aged 88. He was the author of several books; and amongst others, of an *Universal History*, which has been often reprinted.

CHEVRON, or CHEVERON, in heraldry. See HERALDRY.

CHEWING-BALLS, a kind of balls made of a *safetida*, liver of antimony, bay-wood, juniper-wood, and pellitory of Spain; which being dried in the sun, and wrapped in a linen cloth, are tied to the bit of the bridle for the horse to chew; they create an appetite; and it is said, that balls of Venice-treacle may be used in the same manner with good success.

CHEYKS. See BENGAL, n° 17.

CHEYNE (Dr George), a physician of great learning and abilities, born in Scotland in 1671, and educated at Edinburgh under the great Dr Pitcairn. He passed his youth in close study, and with great temperance: but coming to settle at London, when about 30, and finding the younger gentry and free-livers to be the most easy of access and most susceptible of friendship, he changed on a sudden his former manner of living in order to force a trade, having observed this method to succeed with some others. The consequence was, that he grew daily in bulk, and in intimacy with his gay acquaintance; swelling to such an enormous size, that he exceeded 32 stone weight; and he was forced to have the whole side of his chariot made open to receive him into it; he grew short-breathed, lethargic, nervous, and scorbutic; so that his life became an intolerable burden. In this deplorable condition, after having tried all the power of medicine in vain, he resolved to try a milk and vegetable diet; the good effects of which quickly appeared. His size was reduced almost a third; and he recovered his strength, activity, and cheerfulness, with the perfect use of all his faculties. In short, by a regular adherence to this regimen, he lived to a mature period, dying at Bath in 1742, aged 72. He wrote several treatises that were well received; particularly, "An Essay on Health and Long Life;" and "The English Malady, or a Treatise of Nervous Diseases;" both the result of his own experience. In short, he had great reputation in his own time, both as a practitioner and as a writer; and most of his pieces passed thro' several editions. He is to be ranked among those physicians

Chiabrera
||
Chiavenna.

Chiausi
||
Chick.

physicians who have accounted for the operations of medicines and the morbid alterations which take place in the human body upon mechanical principles. A spirit of piety and of benevolence, and an ardent zeal for the interests of virtue, are predominant throughout his writings. An amiable candour and ingenuousness are also discernible, and which led him to retract with readiness whatever appeared to him to be censurable in what he had formerly advanced. Some of the metaphysical notions which he has introduced into his books, may, perhaps, justly be thought fanciful and ill-grounded; but there is an agreeable vivacity in his productions, together with much openness and frankness, and in general great perspicuity.

CHIABRERA (Gabriel), esteemed the Pindar of Italy, was born at Savona in 1552, and went to study at Rome. The Italian princes, and Urban VIII. gave him public marks of their esteem. He wrote a great number of poems; but his lyric verses are most admired. He died at Savona in 1638, aged 86.

CHIAN EARTH, in pharmacy, one of the medicinal earths of the ancients, the name of which is preserved in the catalogues of the materia medica, but of which nothing more than the name has been known for many ages in the shops.

It is a very dense and compact earth; and is sent hither in small flat pieces from the island of Chios, in which it is found in great plenty at this time. It stands recommended to us as an astringent. They tell us, it is the greatest of all cosmetics; and that it gives a whiteness and smoothness to the skin, and prevents wrinkles, beyond any of the other substances that have been celebrated for the same purposes.

CHIAOUS, a word in the original Turkish, signifying "envoys," are officers to the number of five or six hundred in the grand signior's court, under the command of a chiaous bashi. They frequently meet in the grand vizir's palace, that they may be in readiness to execute his orders, and carry his dispatches into all the provinces of the empire. The chiaous bashi assists at the divan, and introduces those who have business there.

CHIAPA, the capital of a province of the same name in Mexico, situated about 300 miles east of Acapulco. W. Long. 98. 0. N. Lat. 16. 30.

CHIAPA *el Real*, a town of Mexico, in a province of the same name, with a bishop's see. Its principal trade consists in chocolate-nuts, cotton, and sugar. W. Long. 98. 35. N. Lat. 16. 20.

CHIAPAS *de los Indos*, a large and rich town of North America, in Mexico, and in a province of the same name. The governor and most of the inhabitants are originally Americans. W. Long. 98. 5. N. Lat. 15. 6.

CHIARI (Joseph), a celebrated Italian painter, was the disciple of Carlo Maratti; and adorned the churches and palaces of Rome with a great number of fine paintings. He died of an apoplexy in 1727, aged 73.

CHIARI, a town of Italy, in the province of Brescia, and territory of Venice, 7 miles west of Brescia, and 27 east of Milan. Here the Imperialists gained a victory over the French in 1701. E. Long. 18. 18. N. Lat. 45. 30.

CHIARO-SCURO. See *CLARO-Obscuro*.

CHIAVENNA, a handsome, populous, and large

town of Switzerland, in the country of the Grisons. It is a trading place, especially in wine and delicate fruits. The governor's palace and the churches are very magnificent, and the inhabitants are Roman Catholics. It is seated near the lake Como. E. Long. 9. 29. N. Lat. 46. 15.

CHIAUSI, among the Turks, officers employed in executing the vizirs, bashaws, and other great men: the orders for doing this, the grand signior sends them wrapped up in a black cloth; on the reception of which, they immediately perform their office.

CHICANE, or CHICANERY, in law, an abuse of judiciary proceeding, tending to delay the cause, to puzzle the judge, or impose upon the parties.

CHICANE, in the schools, is applied to vain sophisms, distinctions, and subtleties, which protract disputes, and obscure the truth.

CHICHESTER, the capital city of the county of Sussex, was built by Cissa, the 2d king of the South Saxons, and by him called *Cissan Caester*. It is surrounded with a wall, which has four gates, answering to the four cardinal points; from which run two streets, that cross one another in the middle and form a square, where the market is kept, and where there is a fine stone piazza built by bishop Read. The space between the west and south gates is taken up with the cathedral church and the bishop's palace. It has five parish-churches; and is seated on the little river Lavant, which washes it on all sides except the north. This city would have been in a much more flourishing condition if it had been built by the sea-side; however, the inhabitants have endeavoured to supply this defect in some measure, by cutting a canal from the city down into the bay. The principal manufactures of the town are malt and needles. The market of Chichester is noted for fish, wheat, barley, malt, and oats: the finest lobsters in England are bred in the Lavant; and it is observable, that this river, unlike most others, is very low in winter, but in summer often overflows its banks. Chichester is a city and county of itself; it is governed by a mayor, recorder, aldermen, common-council without limitation, and four justices of the peace chosen out of the aldermen; and it sends two members to parliament. It is a bishop's see. The cathedral church was anciently dedicated to St Peter. It was new built by Radulph, the twenty-fifth bishop; but being destroyed by fire, it was again built by Seffridus II. the twenty-ninth bishop. This see hath yielded to the church two saints, and to the nation three lord chancellors, two almoners, and one chancellor to the university of Oxford. Anciently the bishops of Chichester were confessors to the queens of England. This diocese contains the whole of the county of Sussex (excepting 22 parishes, peculiars of the archbishop of Canterbury), wherein are 250 parishes, whereof 112 are impropriated. It hath two archdeacons, viz. of Chichester and Lewes; is valued in the king's books at L. 677:1:3, and is computed to be worth annually L. 2600. The tenths of the whole clergy is L. 287:2:0½. To the cathedral belong a bishop, a dean, two archdeacons, a treasurer, a chancellor, thirty-two prebendaries, a chanter, twelve vicars-choral, and other officers. W. Long. 50. N. Lat. 50. 50.

CHICK, or CHICKEN, in zoology, denotes the young

Chick-
weed
||
Chigi.

young of the gallinaceous order of birds, especially the common hen. See PHASIANUS.

CHICK-Weed, in botany. See ALSINE.

CHICKEN-Pox. See (*Index subjoined to*) MEDICINE.

CHICKLING-PEA, in botany, a name given to the LATHYRUS.

CHICUITOS, a province of South America, in the government of Santo-Cruz de la Sierra. The chief riches consist of honey and wax; and the original inhabitants are very voluptuous, yet very warlike. They maintained bloody wars with the Spaniards till 1690; since which, some of them have become Christians. It is bounded by la Plata on the N. E. and by Chili on the W.

CHIDLEY, or CHIMLEY, a market-town of Devonshire, situated in W. Long. 4. 0. N. Lat. 51. 0.

CHIEF, a term signifying the head or principal part of a thing or person. Thus we say, the chief of a party, the chief of a family, &c. The word is formed of the French *chef*, "head;" of the Greek κεφαλη, *caput*, "head;" though Menage derives it from the Italian *capo*, formed of the Latin *caput*.

CHIEF, in heraldry, is that which takes up all the upper part of the escutcheon from side to side, and represents a man's head. *In chief*, imports something borne in the chief part or top of the escutcheon.

CHIEFTAIN, denotes the captain or chief of any class, family, or body of men. Thus the chieftains or chiefs of the Highland clans, were the principal noblemen or gentlemen of their respective clans. See CLANS.

CHIELEFA, a strong town of Turkey in Europe, in the Morea. It was taken by the Venetians in 1685; but after that the Turks retook it, with all the Morea. E. Long. 22. 21. N. Lat. 26. 50.

CHIGI (Fabio), or Pope Alexander VII. was born at Sienna in 1599. His family finding him a hopeful youth, sent him early to Rome, where he soon engaged in a friendship with the marquis Pallavicini, who recommended him so effectually to Pope Urban VIII. that he procured him the post of Inquisitor at Malta. He was sent vice-legate to Ferrara, and afterward nuncio into Germany: there he had an opportunity of displaying his intriguing genius; for he was mediator at Munster, in the long conference held to conclude a peace with Spain. Cardinal Mazarin had some resentment against Chigi, who was soon after made a cardinal and secretary of state by Innocent X. but his resentment was sacrificed to political views. In 1655, when a pope was to be chosen, Cardinal Sacchetti, Mazarin's great friend, finding it was impossible for him to be raised into St Peter's chair because of the powerful opposition made by the Spanish faction, desired Cardinal Mazarin to consent to Chigi's exaltation. His request was granted, and he was elected pope by the votes of all the 64 cardinals who were in the conclave: an unanimity of which there are but few instances in the election of popes. He showed uncommon humility at his election, and at first forbade all his relations to come to Rome without his leave; but he soon became more favourable to his nephews, and loaded them with favours. It is asserted that he had once a mind to turn Protestant. The news-papers in Holland bestowed great encomiums upon him; and acquainted the world, that he did not approve of the cruel persecutions of the Wal-

deneses in Piedmont. There is a volume of his poems extant. He loved the *Belles-Lettres*, and the conversation of learned men. He was extremely fond of stately buildings: the grand plan of the college *Della Sapienza*, which he finished, and adorned with a fine library, remains a proof of his taste in architecture. He died in 1667.

CHILBLAIN, (*pernio*), in medicine, a tumour affecting the feet and hands; accompanied with an inflammation, pains, and sometimes an ulcer or solution of continuity: in which case it takes the denomination of *chaps* on the hands, and of *kibes* on the heels. Chilblain is compounded of *chill* and *blain*; *q. d.* a blain or sore contracted by cold. *Pernio* is the Latin name adopted by physicians; and is derived by Vossius from *perna* "a gammon of bacon," on account of some resemblance. *Chap* alludes to *gape*, both in sound and appearance. *Kibes*, in Welch *kibws*, may be derived from the German *kerben*, "to cut;" the skin, when broke, appearing like a cut.

Chilblains are occasioned by excessive cold stopping the motion of the blood in the capillary arteries. See the article PERNIO.

CHILD, a term of relation to *parent*. See PARENT and CHILDREN.

Bartholine, Paré, Licetus, and many other writers, give an account of a petrified child, which has seemed wholly incredible to some people. The child, however, which they describe, is still in being; and is kept as a great rarity in the king of Denmark's museum at Copenhagen. The woman who was big with this, lived at Sens in Champaign in the year 1582; it was cut out of her belly, and was universally supposed to have lain there about 20 years. That it is a real human foetus, and not artificial, is evident to the eyes of any observer; and the upper part of it, when examined, is found to be of a substance resembling the gypsum, or stone whereof they make the plaster of Paris: the lower part is much harder; the thighs and buttocks being a perfect stone of a reddish colour, and as hard as common quarry-stone: the grain and surface of this part appears exactly like that of the calculi, or stones taken out of human bladders: and the whole substance examined ever so nearly, and felt ever so carefully, appears to be absolute stone. It was carried from Sens to Paris, and there purchased by a goldsmith of Venice; and Frederic III. king of Denmark, purchased it of this man at Venice for a very large sum, and added it to his collection of rarities.

CHILD-Bed, } See MIDWIFERY.
CHILD-Birth. }

CHILD-Wit, a power to take a fine of a bond-woman unlawfully gotten with child, that is, without consent of her lord. Every reputed father of a base child got within the manor of Writtel in Essex, pays to the lord a fine of 3s. 4d.; where, it seems, child-wit extends to free as well as bond women.

CHILDERMAS-DAY, or INNOCENT'S Day, an anniversary held by the church of England on the 28th of December, in commemoration of the children of Bethlehem massacred by order of Herod.

CHILDREN, the plural of CHILD.

Mr Derham computes, that marriages, one with another, produce four children, not only in England, but in other parts also.

Chilblain
||
Children.

Children.

Chili.

In the genealogical history of Tuscany, wrote by Gamarini, mention is made of a nobleman of Sienna, named Pichi, who of three wives had 150 children; and that, being sent ambassador to the pope and the emperor, he had 48 of his sons in his retinue. In a monument in the church-yard of St Innocent, at Paris, erected to a woman who died at 88 years of age, it is recorded, that she might have seen 288 children directly issued from her. This exceeds what Hake-well relates of Mrs Honeywood, a gentlewoman of Kent, born in the year 1527, and married at 16 to her only husband R. Honeywood, of Charing, Esq; and died in her 93d year. She had 16 children of her own body; of which three died young, and a fourth had no issue: yet her grandchildren, in the second generation, amounted to 114; in the third, to 228; though in the fourth, they fell to 9. The whole number she might have seen in her life-time, being 367. $16 + 114 + 228 + 9 = 367$. So that she could say the same as the distich does of one of the Dalburg's family at Basil:

1 2 3 4
Mater ait natae dic natae filia natam,

5 6
Ut moneat, natae, plangere, filiolum.

Management of CHILDREN. See INFANT.

Overlaying of CHILDREN, is a misfortune that frequently happens; to prevent which, the Florentines have contrived an instrument called *arcuccio*. See AR-
CUCCIO.

CHILDREN are, in law, a man's issue begotten on his wife. As to *illegitimate children*, see BASTARD.

For the legal duties of parents to their children, see the articles PARENT and BASTARD.

As to the duties of children to their parents, they arise from a principle of natural justice and retribution. For to those who gave us existence, we naturally owe subjection and obedience during our minority, and honour and reverence ever after: they who protected the weakness of our infancy, are intitled to our protection in the infirmity of their age; they who by sustenance and education have enabled their offspring to prosper, ought, in return, to be supported by that offspring, in case they stand in need of assistance. Upon this principle proceed all the duties of children to their parents, which are enjoined by positive laws. And the Athenian laws carried this principle into practice with a scrupulous kind of nicety: obliging all children to provide for their father when fallen into poverty; with an exception to spurious children, to those whose chastity had been prostituted with consent of their father, and to those whom he had not put in any way of gaining a livelihood. The legislature, says baron Montesquieu, considered, that, in the first case, the father, being uncertain, had rendered the natural obligation precarious; that, in the second case, he had sullied the life he had given, and done his children the greatest of injuries, in depriving them of their reputation; and that, in the third case, he had rendered their life (so far as in him lay) an insupportable burden, by furnishing them with no means of subsistence.

Our laws agree with those of Athens, with regard to the first only of these particulars, the case of spurious issue. In the other cases, the law does not hold

the tie of nature to be dissolved by any misbehaviour of the parent; and therefore a child is equally justifiable in defending the person, or maintaining the cause or suit, of a bad parent as of a good one; and is equally compellable, if of sufficient ability, to maintain and provide for a wicked and unnatural progenitor, as for one who has shown the greatest tenderness and parental piety. See further the article *FILIAL Affection*.

CHILI, a province of South America, bounded by Peru on the north, by the province of La Plata on the east, by Patagonia on the south, and by the Pacific ocean on the west, lying between 75 and 85 degrees of west longitude, and between 25 and 45 degrees of south latitude; though some comprehend in this province Patagonia and Terra del Fuego.

The first attempt of the Spaniards upon this country was made by Almagro in the year 1535, after he and Pizaro had completed the conquest of Peru. He set out on his expedition to Chili with a considerable body of Spaniards and auxiliary Indians. For 200 leagues he was well accommodated with every necessary by the Indians, who had been subjects of the emperors of Peru: but reaching the barren country of Charcas, his troops became discontented through the hardships they suffered; which determined Almagro to climb the mountains called Cordilleras, in order to get the sooner into Chili; being ignorant of the invaluable mines of Potosi, contained in the province of Charcas where he then was. At that time the Cordilleras were covered with snow, the depth of which obliged him to dig his way through it. The cold made such an impression on his naked Indians, that it is computed no less than 10,000 of them perished on these dreadful mountains, 150 of the Spaniards sharing the same fate; while many of the survivors lost their fingers and toes through the excess of cold. At last, after encountering incredible difficulties, Almagro reached a fine, temperate, and fertile plain on the opposite side of the Cordilleras, where he was received with the greatest kindness by the natives. These poor savages, taking the Spaniards for deputies of their god Virachoca, immediately collected for them an offering of gold and silver worth 200,000 ducats: and soon after brought a present to Almagro worth 300,000 more. These offerings only determined him to conquer the whole country as soon as possible. The Indians among whom he now was, had acknowledged the authority of the Peruvian incas, or emperors, and consequently gave Almagro no trouble. He therefore marched immediately against those who had never been conquered by the Peruvians, and inhabited the southern parts of Chili. These savages fought with great resolution, and disputed every inch of ground: but in five months time the Spaniards had made such progress, that they must infallibly have reduced the whole province in a very little time, had not Almagro returned to Peru, in consequence of a commission sent him from Spain.

In 1540, Pizaro having overcome and put Almagro to death, sent into Chili, Baldivia or Valdivia, who had learned the rudiments of war in Italy, and was reckoned one of the best officers in the Spanish service. As he penetrated southwards, however, he met with much opposition; the confederated caziques frequently gave him battle, and displayed great cou-

rage

Chili.

rage and resolution; but could not prevent him from penetrating to the valley of Mafiocho, which he found incredibly fertile and populous. Here he founded the city of St Jago; and finding gold mines in the neighbourhood, forced the Indians to work in them; at the same time building a castle for the safety and protection of his new colony. The natives, exasperated at this slavery, immediately took up arms; attacked the fort; and, though defeated and repulsed, set fire to the outworks, which contained all the provisions of the Spaniards. Nor were they discouraged by this and many other defeats, but still continued to carry on the war with vigour. At last, Valdivia, having overcome them in many battles, forced the inhabitants of the vale to submit; upon which he immediately set them to work in the mines of Quilotta. This indignity offered to their countrymen redoubled the fury of those who remained at liberty. Their utmost efforts, however, were as yet unable to stop Valdivia's progress. Having crossed the large rivers Maule and Hata, he traversed a vast tract of country, and founded the city of La Concepcion on the South-sea-coast. He erected fortresses in several parts of the country, in order to keep the natives in awe; and built the city called *Imperial*, about 40 leagues to the southward of Concepcion. The Spanish writers say, that the neighbouring valley contained 80,000 inhabitants of a peaceable disposition; and who were even so tame as to suffer Valdivia to parcel out their lands among his followers, while they themselves remained in a state of inactivity. About 16 leagues to the eastward of Imperial, the Spanish general laid the foundations of the city *Villa Rica*, so called on account of the rich gold mines he found there. But his ambition and avarice had now involved him in difficulties from which he could never be extricated: He had extended his conquests beyond what his strength was capable of maintaining. The Chileans were still as desirous as ever of recovering their liberties. The horses, fire-arms, and armour of the Spaniards, indeed, appeared dreadful to them; but thoughts of endless slavery were still more so. In the course of the war they had discovered that the Spaniards were vulnerable and mortal men like themselves; they hoped, therefore, by dint of their superiority in numbers, to be able to expel the tyrannical usurpers. Had all the nations joined in this resolution, the Spaniards had certainly been exterminated; but some of them were of a pacific and fearful disposition, while others considered servitude as the greatest of all possible calamities. Of this last opinion were the Aracceans, the most intrepid people in Chili, and who had given Valdivia the greatest trouble. They all rose to a man, and chose Capaulican, a renowned hero among them, for their leader. Valdivia, however, received notice of their revolt sooner than they intended he should, and returned with all expedition to the vale of Araccea; but before he arrived, 14,000 of the Chileans were there assembled under the conduct of Capaulican. He attacked them with his cavalry, and forced them to retreat into the woods; but could not obtain a complete victory, as they kept continually falling out and harassing his men. At last Capaulican, having observed that fighting with such a number of undisciplined troops only served to contribute to the defeat and confusion of the whole, divided his for-

No 77.

ces into bodies of 1000 each. These he directed to attack the enemy by turns; and, though he did not expect that a single thousand would put them to flight, he directed them to make as long a stand as they could; when they were to be relieved and supported by another body; and thus the Spaniards would be at last wearied out and overcome. The event fully answered his expectations. The Chileans maintained a fight for seven or eight hours, until the Spaniards, growing faint for want of refreshment, retired precipitately. Valdivia ordered them to possess a pass at some distance from the field, to stop the pursuit; but this design being discovered to the Chileans by the treachery of his page, who was a native of that country, the Spaniards were surrounded on all sides, and cut in pieces by the Indians. The general was taken and put to death: some say with the tortures usually inflicted by those savages on their prisoners; others, that he had melted gold poured down his throat; but all agree, that the Indians made flutes and other instruments of his bones, and preserved his skull as a monument of their victory, which they celebrated by an annual festival. After this victory the Chileans had another engagement with their enemies; in which also they proved victorious, defeating the Spaniards with the loss of near 3000 men; and upon this they bent their whole force against the colonies. The city of Concepcion, being abandoned by the Spaniards, was taken and destroyed: but the Indians were forced to raise the siege of Imperial; and their progress was at last stopped by Garcia de Mendoza, who defeated Capaulican, took him prisoner, and put him to death. No defeats, however, could dispirit the Chileans. They continued the war for 50 years; and to this day they remain unconquered, and give the Spaniards more trouble than any other American nation. Their most irreconcilable enemies are the inhabitants of Araccea and Tucapel, those to the south of the river Bobio, or whose country extends towards the Cordilleras.—The manners of these people greatly resemble those of North America, which we have already described under the article AMERICA; but seem to have a more warlike disposition. It is a constant rule with the Chileans never to sue for peace. The Spaniards are obliged not only to make the first overtures, but to purchase it by presents. They have at last been obliged to abandon all thoughts of extending their conquests, and reduced to cover their frontiers by erecting forts at proper distances.

The Spanish colonies in Chili are dispersed on the borders of the South-sea. They are parted from Peru by a desert 80 leagues in breadth; and bounded by the island of Chiloe, at the extremity next the straits of Magellan. There are no settlements on the coast except those of Baldiia, Concepcion island, Valparaíso, and Coquimbo or La Serena, which are all sea-ports. In the inland country is St Jago, the capital of the colony. There is no culture nor habitation at any distance from these towns. The buildings in the whole province are low, made of unburnt brick, and mostly thatched. This practice is observed on account of the frequent earthquakes; and is properly adapted to the nature of the climate, as well as the indolence of the inhabitants.

The climate of Chili is one of the most wholesome in

Chili.

Chili
||
Chiliagon.

in the whole world. The vicinity of the Cordilleras gives it such a delightful temperature as could not otherwise be expected in that latitude. Though gold mines are found in it, their richness has been too much extolled; their produce never exceeds L. 218,750. The soil is prodigiously fertile. All the European fruits have improved in that happy climate. The wine would be excellent if nature were properly assisted by art: and the corn-harvest is reckoned a bad one when it does not yield a hundred fold. With all these advantages, Chili has no direct intercourse with the mother-country. Their trade is confined to Peru, Paraguay, and the savages on their frontiers. With these last they exchange their less valuable commodities, for oxen, horses, and their own children, whom they are ready to part with for the most trifling things. This province supplies Peru with great plenty of hides, dried fruit, copper, salt-meat, horses, hemp, lard, wheat, and gold. In exchange, it receives tobacco, sugar, cocoa, earthen-ware, woollen cloth, linen, hats, made at Quito, and every article of luxury brought from Europe. The ships sent from Callao on this traffic were formerly bound to Conception Bay, but now come to Valparaíso. The commerce between this province and Paraguay is carried on by land, though it is a journey of 300 leagues, 40 of which lie through the snows and precipices of Cordilleras; but if it was carried on by sea, they must either pass the straits of Magellan or double Cape Horn, which the Spaniards always avoid as much as possible. To Paraguay are sent some woollen stuffs called *ponchos*, which are used for cloaks; also wines, brandy, oil, and chiefly gold. In return they receive wax, a kind of tallow fit to make soap, European goods, and negroes.

Chili is governed by a chief, who is absolute in all civil, political, and military affairs, and is also independent of the viceroy. The latter has no authority except when a governor dies; in which case he may appoint one in his room for a time, till the mother-country names a successor. If, on some occasions, the viceroy has interfered in the government of Chili, it was when he has been either authorised by a particular trust reposed in him by the court, or by the deference paid to the eminence of his office; or when he has been actuated by his own ambition to extend his authority. In the whole province of Chili there are not 20,000 white men, and not more than 60,000 negroes, or Indians, able to bear arms. The military establishment amounted formerly to 2000 men; but the maintaining of them being found too expensive, they were reduced to 500 at the beginning of this century.

CHILIAD, an assemblage of several things ranged by thousands. The word is formed of the Greek *χίλις*, *mille*, a thousand.

CHILIAGON, in geometry, a regular plain figure of 100 sides and angles. Though the imagination cannot form the idea of such a figure, yet we may have a very clear notion of it in the mind, and can easily demonstrate that the sum of all its angles is equal to 1996 right ones: for the internal angles of every plane figure are equal to twice as many right ones as the figure hath sides, except those four which are about the centre of the figure, from whence it

VOL. IV. Part II.

may be resolved into as many triangles as it has sides. Chiliarcha
||
Chilo.

The author of *l'Art de Penfer*, p. 44. has brought this instance to show the distinction between imagination and conceiving.

CHILIARCHA, or CHILIARCHUS, an officer in the armies of the ancients, who had the command of a thousand men.

CHILIASTS, in church-history. See MILLENA-RIANS.

CHILLINGWORTH (William), an eminent divine of the church of England, was born at Oxford in 1602, and bred there. He made early great proficiency in his studies, being of a very quick genius. He was an expert mathematician, as well as an able divine, and a very good poet. Study and conversation at the university turning upon the controversy between the church of England and that of Rome, on account of the king's marriage with Henrietta daughter to Henry IV. king of France, Mr Chillingworth forsook the church of England, and embraced the Romish religion. Dr Laud, then bishop of London, hearing of this, and being greatly concerned at it, wrote Mr Chillingworth; who expressing a great deal of candour and impartiality, that prelate continued to correspond with him. This set Mr Chillingworth on a new inquiry; and at last determined him to return to his former religion. In 1634 he wrote a confutation of the arguments which had induced him to go over to the church of Rome. He spoke freely to his friends of all the difficulties that occurred to him; which gave occasion to a groundless report, that he had turned Papist a second time, and then Protestant again. His return to the communion of the church of England made a great noise, and engaged him in several disputes with those of the Romish persuasion. But in 1635 he engaged in a work which gave him a far greater opportunity to confute the principles of the church of Rome, and to vindicate the Protestant religion, under the title of "The Religion of Protestants a safe Way to Salvation." Sir Thomas Coventry, lord keeper of the great seal, offering him preferment, Mr Chillingworth refused to accept it on account of his scruples with regard to the subscription of the 39 articles. However, he at last surmounted these scruples; and being promoted to the chancellorship of the church of Sarum, with the prebend of Brixworth in Northamptonshire annexed to it, he complied with the usual subscription. Mr Chillingworth was zealously attached to the royal party; and, in August 1643, was present in king Charles I.'s army at the siege of Gloucester, where he advised and directed the making certain engines for assaulting the town. Soon after, having accompanied the Lord Hopton, general of the king's forces in the west, to Arundel castle in Sussex, he was there taken prisoner by the parliamentary forces under the command of Sir William Waller, who obliged the castle to surrender. But his illness increasing, he obtained leave to be conveyed to Chichester, where he was lodged at the bishop's palace; and, after a short sickness, died in 1644. He hath left several excellent works behind him.

CHILMINAR. See PERSEPOLIS.

CHILO, one of the seven sages of Greece, and of the ephori of Sparta the place of his birth, flourished about 556 years before Christ. He was accustomed

Chiloe
Chimæra.

to say, that there were three things very difficult: "To keep a secret; to know how best to employ our time; and to suffer injuries without murmuring." According to Pliny, it was he who caused the short sentence, *Know thyself*, to be written in letters of gold in the temple of Delphos. It is said that he died with joy, while embracing his son, who had been crowned at the Olympic games.

CHILOE, an island lying near the coast of Chili, in South America, under the 43d degree of south latitude. It is the chief of an archipelago of 40 islands, and its principal town is Castro. It rains here almost all the year, insomuch that nothing but Indian corn, or some such grain, that requires but little heat to ripen it, can ever come to perfection. They have excellent shell-fish, very good wild-fowl, hogs, sheep, and bees; as also a great deal of honey and wax. They carry on a trade with Peru and Chili; whither they send boards of cedar, of which they have vast forests.

CHILTENHAM, a town in Gloucestershire, six miles from Gloucester; noted for its purgative chalybeate spring, which has rendered it of late years a place of fashionable resort. This water, which operates with great ease, is deemed excellent in scorbutic complaints, and has been used with success in the gravel.

CHILTERN, a chain of chalky hills forming the southern part of Buckinghamshire, the northern part of the county being distinguished by the name of the *Vale*. The air on these heights is extremely healthful: The soil, though stoney, produces good crops of wheat and barley; and in many places it is covered with thick woods, among which are great quantities of beech.—*Chiltern* is also applied to the hilly parts of Berkshire, and it is believed has the same meaning in some other counties. Hence the HUNDREDS lying in those parts are called the *Chiltern Hundreds*.

CHILTERN Hundreds (Stewards of.) Of the Hundreds into which many of the English counties were divided by King Alfred for the better government, the jurisdiction was originally vested in peculiar courts; but came afterwards to be devolved to the county courts, and so remains at present; excepting with regard to some, as the *chilterns*, which have been by privilege annexed to the crown. These having still their own courts, a *Steward* of those courts is appointed by the chancellor of the exchequer, with a salary of 20s. and all fees, &c. belonging to the office: And this is deemed an appointment of such profit, as to vacate a seat in parliament.

CHIMÆRA, a port-town of Turkey in Europe, situated at the entrance of the gulph of Venice, in the province of Epirus, about 32 miles north of the city Corfu, near which are the mountains of Chimæra, which divide Epirus from Thessaly. E. Long. 26. 40. N. Lat. 40. 20.

CHIMÆRA, in fabulous history, a celebrated monster, sprung from Echidna and Typhon. It had three heads; that of a lion, a goat, and a dragon; and continually vomited flames. The foreparts of its body were those of a lion, the middle was that of a goat, and the hinder parts were those of a dragon. It generally lived in Lycia, about the reign of Jobates, by whose orders Bellerophon, mounted on the horse Pegasus, overcame it. This fabulous tradition is explained by the recollection that there was a burning mountain in Lycia, whose top was the resort of lions on

account of its desolate wilderness; the middle, which was fruitful, was covered with goats; and at the bottom the marshy ground abounded with serpents. Bellerophon is said to have conquered the Chimæra, because he destroyed the wild beasts on that mountain, and rendered it habitable. Plutarch says that it was the captain of some pirates who adorned their ship with the images of a lion, a goat, and a dragon.

By a *chimera*, among the philosophers, is understood a mere creature of the imagination, composed of such contradictions and absurdities as cannot possibly any where exist but in thought.

CHIMES of a CLOCK, a kind of periodical music, produced at equal intervals of time, by means of a particular apparatus added to a clock.

In order to calculate numbers for the chimes, and adapt the chime-barrel, it must be observed, that the barrel must turn round in the same time that the tune it is to play requires in singing. As for the chime-barrel, it may be made up of certain bars that run athwart it, with a convenient number of holes punched in them to put in the pins that are to draw each hammer: and these pins, in order to play the time of the tune rightly, must stand upright, or hang down from the bar, some more, some less. To place the pins rightly, you may proceed by the way of changes on bells, viz. 1, 2, 3, 4; or rather make use of the musical notes. Observe what is the compass of your tune, and divide the barrel accordingly from end to end.

Thus, in the examples on Plate CXXXVII. each of the tunes is eight notes in compass; and accordingly the barrel is divided into eight parts. These divisions are struck round the barrel; opposite to which are the hammer-tails.

We speak here as if there were only one hammer to each bell, that it may be more clearly apprehended; but when two notes of the same sound come together in a tune, there must be two hammers to the bell to strike it: so that if in all the tunes you intend to chime of eight notes compass, there should happen to be such double notes on every bell, instead of eight you must have sixteen hammers; and accordingly you must divide the barrel, and strike sixteen strokes round it, opposite to each hammer-tail: then you are to divide it round about into as many divisions as there are musical bars, semibreves, minims, &c. in the tune.

Thus the hundredth-psalm tune has 20 semibreves, and each division of it is a semibreve: the first note of it also is a semibreve; and, therefore, on the chime-barrel must be a whole division, from five to five; as you may understand plainly, if you conceive the surface of a chime-barrel to be represented by the above figures, as if the cylindrical superficies of the barrel were stretched out at length, or extended on a plane: and then such a table, so divided, if it were to be wrapped round the barrel, would show the places where all the pins are to stand in the barrel; for the dots running about the table are the places of the pins that play the tune.

Indeed, if the chimes are to be complete, you ought to have a set of bells to the gamut notes; so as that each bell having the true sound of *sol, la, mi, fa*, you may play any tune with its flats and sharps: nay, you may by this means play both the bass and treble with one barrel: and by setting the names of your bells at

the

Chimney. the head of any tune, that tune may easily be transferred to the chime-barrel, without any skill in music: but it must be observed, that each line in the music is three notes distant; that is, there is a note between each line, as well as upon it.

CHIMNEY, in architecture, a particular part of a house, where the fire is made, having a tube or funnel to carry off the smoke. The word *chimney* comes from the French *cheminée*; and that from the Latin *caminata*, "a chamber wherein is a chimney:" *caminata*, again, comes from *caminus*; and that from the Greek *καμινος*, "a chimney;" of *καίω*, *uro* "I burn."

Chimneys are usually supposed a modern invention; the ancients only making use of stoves: but Octavio Ferrari endeavours to prove chimneys in use among the ancients. To this end, he cites the authority of Virgil,

Et jam summa procul villarum culmina fumant:
and that of Appian, who says, "That of those persons proscribed by the triumvirate, some hid themselves in wells and common sewers, and some on the tops of houses and chimneys;" for so he understands *κατακρυβήσας ὑποσώτας, fumaria sub tecto posita*. Add, that Aristophanes, in one of his comedies, introduces his old man, Polycleon, shut up in a chamber, whence he endeavours to make his escape by the chimney. However, the few instances remaining among the ancients, together with the obscurity of the rules of Vitruvius on this head, make us rather conclude the use of stoves, whereof the ancients had entire apartments, induced them to neglect this part of building which the coldness of our climates obliges us to have a principal regard to.

Method of Building CHIMNEYS that will not smoke. Workmen have different methods of drawing up the funnels of chimneys, generally according to their own fancies and judgments, and sometimes according to the customs of places. They are seldom directed by sound and rational principles. It will be found for the most part, that the smoking of chimneys is owing to their being carried up narrower near the top than below, or zig-zag, all in angles: in some cases, indeed, it is owing to accidental causes; but, for the most part, to those two above mentioned. Where they are carried up in the pyramid or tapering form, especially if the house be of a considerable height, it is ten to one but they sometimes smoke. The air in the rooms, being rarified, is forced into the funnel of the chimney, and receives from the fire an additional force to carry up the smoke. Now it is evident, that the further up the smoke flies, the less is the force that drives it, the slower it must move, and consequently the more room in proportion it should have to move in; whereas in the usual way it has less, by the sides of the chimney being gathered closer and closer together.

The method here proposed of carrying up chimneys will be objected to by some thus: The wider a chimney is at the top, say they, the more liberty has the wind to blow down. Very true; but is it not resisted in going down, both by the form of the chimney and other evident causes, so that it must return again? In the other way, when the wind blows down, the resistance being less, the wind and smoke are, if we may use the expression, imprisoned, and make the

smoke puff out below. This method has proved effectual after all others had failed; and that in a house placed in the worst situation possibly, namely, under a high mountain to the southward, from which strong blasts blow down upon it. A vent was carried up without angles, as perpendicular as possible; and was made about three or four inches wider at top than at the bottom: the funnel was gathered in a throat directly above the fire-place, and so widening upwards. Since that time the house has not only ceased to smoke, but, when the doors stand open, the draught is so strong that it will carry a piece of paper out at the chimney-head. See more on this subject under the article **SMOKE**.

CHIMNEY-Money, otherwise called *Hearth-money*, a duty to the crown on houses. By stat. 14. Char. II. cap. 2. every fire-hearth, and stove of every dwelling or other house, within England and Wales (except such as pay not to church and poor), was chargeable with 2 s. *per annum*, payable at Michaelmas and Lady-day to the king and his heirs and successors, &c.; which payment was commonly called *chimney-money*. This tax, being much complained of as burdensome to the people, has been since taken off, and others imposed in its stead; among which that on windows has by some been esteemed almost equally grievous.

CHIMPANZEE, in natural history. See **SIMIA**.

CHINA, a country of Asia, situated on the most easterly part of that continent. It is bounded on the north by Tartary; from which it is divided, partly by a prodigious wall of 1500 miles in length, and partly by high, craggy, and inaccessible mountains. On the east, it is bounded by the ocean; on the west, by part of the Mogul's empire, and India beyond the Ganges, from which it is parted by other ridges of high mountains and sandy deserts. On the south, it is bounded partly by the kingdoms of Lao, Tonquin, Ava, and Cochin-China, and partly by the southern or Indian sea, which flows between it and the Philippine islands. There are several ways of computing its length and breadth. According to some of these, it is reckoned 1269, 1600, or 1800 miles in length, and as much in breadth: however, by the best and latest accounts, this vast country is somewhat of an oval form, the breadth being less than the length by little more than a fourth-part. It contains 15 provinces, exclusive of that of Lyau-tong, which is situated without the great wall, though under the same dominion. Their names are, 1. Shenfi; 2. Shanfi; 3. Pecheli; which are situated on the north side, along the wall. 4. Shantung; 5. Kyan-nang; 6. Che-kyang; 7. Fo-kyen; which are situated along the eastern ocean. 8. Quang-tong; 9. Quangsi; 10. Yu-nan; 11. Se-chuen; which stretch themselves towards the south and south-west. And, 12. Ho-nan; 13. Hu-quand; 14. Quey-chew; 15. Kyang-si: which take up the middle part. For a particular description of all these, see their proper articles.

The origin of all nations is involved in obscurity and fable; but that of the Chinese much more so than any other. Every nation is inclined to assume too high an antiquity to itself, but the Chinese carry theirs beyond all bounds. Indeed, though no people on earth are more exact in keeping records of every memorable

Why their
history is
so uncer-
tain.

morable transaction, yet such is the genius of the Chinese for superstition and fable, that the first part of their history is deservedly contemned by every rational person. What contributes more to the uncertainty of the Chinese history is, that neither we, nor they themselves, have any thing but fragments of their ancient historical books; for about 213 years before Christ, the reigning emperor of Si-whang-ti caused all the books in the empire to be burned, except those written by lawyers and physicians. Nay, the more effectually to destroy the memory of every thing contained in them, he commanded a great number of learned men to be buried alive, lest, from their memories, they should commit to writing something of the true memoirs of the empire. The inaccuracy of the Chinese annals is complained of even by their most respected author, Confucius himself; who also affirms, that, before his time, many of the oldest materials for writing such annals had been destroyed.

5
Fabulous
history of
China.

According to the Chinese histories, the first monarch of the whole universe (that is, of China), was called *Puon-ku*, or *Puen-cu*. This, according to some, was the first man; but according to Bayer and Menzelius, two of the greatest critics in Chinese literature that have hitherto appeared, the word signifies *the highest antiquity*. *Puon-ku* was succeeded by *Tiene-hoang*, which signifies *the emperor of heaven*. They call him also the intelligent heaven, the supreme king of the middle heaven, &c. According to some of their historians, he was the inventor of letters, and of the Cyclic characters by which they determine the place of the year, &c. *Tiene-hoang* was succeeded by *Ti-hoang* (the emperor of the earth), who divided the day and night, appointing 30 days to make one moon, and fixed the winter solstice to the 11th moon. *Ti-hoang* was succeeded by *Gine-hoang* (sovereign of men), who with his nine brothers shared the government among them. They built cities, and surrounded them with walls; made a distinction between the sovereign and subjects; instituted marriage, &c.

The reigns of these four emperors make up one of what the Chinese called *ki*, "ages," or "periods," of which there were nine before *Fo-hi*, whom their most sensible people acknowledge as the founder of their empire.

The history of the second *ki* contradicts almost every thing said of the first; for though we have but just now been told that *Gine-hoang* and his brethren built cities surrounded with walls; yet, in the succeeding age, the people dwelt in caves, or perched upon trees as it were in nests. Of the third *ki* we hear nothing; and in the fourth, it seems matters had been still worse, as we are told that men were then only taught to retire into the hollows of rocks. Of the fifth and sixth we have no accounts. These six periods, according to some writers, contained 90,000 years; according to others, 1,100,750.

In the seventh and eighth *ki*, they tell us over again what they had said of the first; namely, that men began to leave their caves and dwell in houses, and were taught to prepare clothes, &c. *Tchine-fang*, the first monarch of the eighth *ki*, taught his subjects to take off the hair from skins with rollers of wood, and cover themselves with the skins so prepared. He taught

them also to make a kind of web of their hair, to serve as a covering to their heads against rain. They obeyed his orders with joy, and he called his subjects *people clothed with skins*. His reign lasted 350 years; that of one of his successors, also, named *Yeou-tsao-chi*, lasted more than 300; and his family continued for 12 or 18,000 years. But what is very surprising, all these thousands and millions of years had elapsed without mankind's having any knowledge of fire. This was not discovered till towards the close of this period, by one *Souigine*. After so useful a discovery, he taught the people to dress their victuals; whereas before, they had devoured the flesh of animals quite raw, drank their blood, and swallowed even their hair and feathers. He is also said to have been the inventor of fishing, letters, &c.

In the ninth period we find the invention, or at least the origin of letters, attributed to one *Tsang-hie*, who received them from a divine tortoise that carried them on his shell, and delivered them into the hands of *Tsang-hie*. During this period also, music, money, carriages, merchandize, and commerce, &c. were invented. There are various calculations of the length of these *ki* or periods. Some make the time from *Puan-ku* to Confucius, who flourished about 479 years before Christ, to contain 279,000 years; others, 2,276,000; some, 2,759,860 years; others, 3,276,000; and some no less than 96,961,740 years.

These extravagant accounts are by some thought to contain obscure and imperfect hints concerning the cosmogony and creation of the world, &c. *Puon-ku*, the first emperor, they think, represents eternity preceding the duration of the world. The succeeding ones, *Tiene-hoang*, *Ti-hoang*, and *Gine-hoang*, they imagine, signify the creation of the heavens and earth, and the formation of man. The ten *ki*, or ages, nine of which preceded *Fo-hi*, mean the ten generations preceding Noah. This may very possibly be the case; for about 300 years before Christ, some Jews travelled into China, who might have made the Mosaic writings known there.

What we have now related, contains the substance of that part of the Chinese history which is entirely fabulous. After the nine *ki* or "ages" already taken notice of, the tenth commenced with *Fo-hi*; and the history, though still very dark, obscure, and fabulous, begins to grow somewhat more consistent and intelligible. *Fo-hi* was born in the province of Shen-si. His mother walking upon the bank of a lake in that province, saw a very large print of a man's foot in the sand there; and, being surrounded by an iris or rainbow, became impregnated. The child was named *Fo-hi*; and, when he grew up, was by his countrymen elected king on account of his superior merit, and styled *Tyent-tse*, that is "the son of heaven." He invented the eight *qua*, or symbols, consisting of three lines each, which, differently combined, formed 64 characters that were made use of to express every thing. To give these the greater credit, he pretended that he had seen them inscribed on the back of a dragon-horse (an animal shaped like a horse, with the wings and scales of a dragon), which arose from the bottom of a lake. Having gained great reputation among his countrymen by this prodigy, he is said to have created

China.

plained.

7
Reign of
Fo-hi.

manda-

China. mandarins or officers, under the name of *dragons*. Hence we may assign a reason why the emperors of China always carry a dragon in their banners. He also instituted marriage, invented music, &c. Having established a prime minister, he divided the government of his dominions among four mandarins, and died after a reign of 115 years.

8 Miraculous
solstice. After Fo-hi followed a succession of emperors, of whom nothing remarkable is recorded, except that in the reign of *Tau*, the seventh after Fo-hi, the sun did not set for ten days, so that the Chinese were afraid of a general conflagration. This event the compilers of the Universal History take to be the same with that mentioned in the book of Joshua, when the sun and moon stood still for about the space of a day. Fo-hi, they will have to be the same with Noah. They imagine, that after the deluge, this patriarch remained some time with his descendents; but on their wicked combination to build the tower of Babel, he separated himself from them with as many as he could persuade to go along with him; and that, still travelling eastward, he at last entered the fertile country of China, and laid the foundation of that vast empire.—But, leaving these fabulous and conjectural times, we shall proceed to give some account of that part of the Chinese history, which may be more certainly depended on.

As the Chinese, contrary to the practice of almost all nations, have never sought to conquer other countries, but rather to improve and content themselves with their own, their history for many ages furnishes nothing remarkable. The whole of their emperors, abstracting from those who are said to have reigned in the fabulous times, are comprehended in 22 dynasties, mentioned in the following table.

	Emperors.	Before Christ.
1. <i>Hya</i> , containing	17	2207.
2. <i>Shang</i> , or <i>Ing</i> ,	28	1766.
3. <i>Chew</i> ,	35	1122.
4. <i>Tsin</i> ,	4	248.
5. <i>Han</i> ,	25	206.
		After Christ.
6. <i>Hew-han</i> ,	2	220.
7. <i>Tsin</i> ,	15	465.
8. <i>Song</i> ,	8	220.
9. <i>Tsi</i> ,	5	479.
10. <i>Lyang</i> ,	4	502.
11. <i>Chin</i> ,	4	557.
12. <i>Swi</i> ,	3	
13. <i>Twang</i> ,	20	618.
14. <i>Hew-lyang</i> ,	2	907.
15. <i>Hew-tang</i> ,	4	923.
16. <i>Hew-tsin</i> ,	2	936.
17. <i>Hew-han</i> ,	2	947.
18. <i>Hew-chew</i> ,	3	951.
19. <i>Song</i> ,	18	960.
20. <i>Lwen</i> ,	9	1280.
21. <i>Ming</i> ,	16	1368.
22. <i>Tsing</i> ,		1645.

This table is formed according to the accounts of the Jesuit Du Halde, and is commonly reckoned to be the most authentic; but according to the above mentioned hypothesis of the compilers of the Universal History, who make *Tau* cotemporary with Joshua, the

dynasty of *Hya* did not commence till the year before Christ 1357; and to accommodate the history to their hypothesis, great alterations must be made in the duration of the dynasties.

The most interesting particulars of the Chinese history relate only to the incursions of the Tartars, who at last conquered the whole empire, and who still continue to hold the sovereignty; though by transferring the seat of the empire to Peking, and adopting the Chinese language, manners, &c. Tartary would seem rather to have been conquered by China, than China by Tartary. These incursions are said to have begun very early; even in the time of the emperor Shun, successor to Yau above mentioned, in whose reign the miraculous solstice happened. At this time, the Tartars were repulsed, and obliged to retire into their own territories. From time to time, however, they continued to threaten the empire with invasions, and the northern provinces were often actually ravaged by the Tartars in the neighbourhood. About the year before Christ 213, Shi-whang-ti, having fully subdued all the princes, or kings as they were called, of the different provinces, became emperor of China with unlimited power. He divided the whole empire into 36 provinces; and finding the northern part of his dominions much incommoded by the invasions of the neighbouring barbarians, he sent a formidable army against them, which drove them far beyond the boundaries of China. To prevent their return, he built the famous wall already mentioned, which separates China from Tartary. After this, being elated with his own exploits, he formed a design of making posterity believe that he himself had been the first Chinese emperor that ever sat on the throne. For this purpose, he ordered all the historical writings to be burnt, and caused many of the learned to be put to death, as already mentioned.

What effect the great wall for some time had in preventing the invasions of the Tartars, we are not told; but in the tenth century of the Christian æra, those of Kitan or Lyau got a footing in China. The Kitan were a people of eastern Tartary, who dwelt to the north and north-east of the province of Pecheli in China, particularly in that of Layu-tong lying without the great wall. These people having subdued the country between Korea and Kashgar, became much more troublesome to the Chinese than all the other Tartars. Their empire commenced about the year 916, in the fourth year of Mo-ti-kyan-ti, second emperor of the 14th Chinese dynasty called *Hew-lyang*. In 946, Mingt-song, second emperor of the 15th dynasty, being dead, Sheking-tang, his son-in-law, rebelled against Mingt-song, his son and successor, whom he deprived of his crown and life. This he accomplished by means of an army of 50,000 men furnished by the Kitan. Fi-ti, the son of Mingt-song, being unable to resist the usurper, fled to the city Ghey-chew; where shutting himself up with his family and all his valuable effects, he set fire to the palace and was burnt to ashes. On his death, Sheking-tang assumed the title of emperor; founded the 16th dynasty; and changed his name to that of *Kaut-su*. But the Kitan general refusing to acknowledge him, he was obliged to purchase

chase a peace by yielding up to the Tartars 16 cities in the province of Pecheli, besides a yearly present of 300,000 pieces of silk.

This submission served only to inflame the avarice and ambition of the Kitan. In 959, they broke the treaty when least expected, and invaded the empire afresh. Tsi-vang, the emperor at that time, opposed them with a formidable army; but through the treachery of his general Lyew-chi-ywen, the Tartars were allowed to take him prisoner. On this, Tsi-vang was glad to recover his liberty by accepting of a small principality; while the traitor became emperor of all China, and, changing his name to *Kaut-su*, founded the 17th dynasty. The Tartars, in the mean time, ravaged all the northern provinces without opposition, and then marched into the southern. But being here stopped by some bodies of Chinese troops, the general thought proper to retire with his booty into Tartary. In 962, Kaut-su dying, was succeeded by his son In-ti. The youth of this prince gave an opportunity to the eunuchs to raise commotions; especially as the army was employed at a distance in repelling the invasions of the Tartars. This army was commanded by Ko-ghey, who defeated the enemy in several battles, and thus restored peace to the northern provinces. In the mean time, In-ti was slain by his eunuchs, and the empress placed his brother on the throne: but Ko-ghey, returning in triumph, was saluted emperor by his victorious army, and the empress being unable to support the rights of her son, was obliged to submit, while Ko-ghey, assuming the name of *Tay-tsu*, founded the 18th dynasty. Nine years after this, however, the grandees of the empire, setting aside Kong-ti, the third in succession from Tay-tsu, on account of his non-age, proclaimed his guardian, named *Chan-quang-yu*, emperor; who, assuming the name of *Kau-tsu*, founded the 19th dynasty, called *Song*, or *Tsong*.

Under this monarch the empire began to recover itself; but the Kitan still continued their incursions. The successors of Kau-tsu opposed them with various success; but at last, in 978, the barbarians became so strong as to lay siege to a considerable city. Tay-tsong, successor to Kau-tsu, detached 300 soldiers, each carrying a light in his hand, against them in the night-time, with orders to approach as near as possible to the Tartar camp. The barbarians, imagining, by the number of lights, that the whole Chinese army was at hand, immediately fled, and, falling into the ambuscades laid for them by the Chinese general, were almost all cut to pieces.

This check, however, did not long put a stop to the ravages of the Kitan. In the year 999, they laid siege to a city in the province of Pecheli; but Ching-tsong, successor to Tay-tsong, came upon them with his army so suddenly, that they betook themselves to flight. The emperor was advised to take advantage of their consternation, and recover the country which had been yielded to them; but instead of pursuing his victory, he bought a peace, by consenting to pay annually 100,000 tael (about L. 34,000), and 200,000 pieces of silk. The youth and pacific disposition of Jin-tsong, successor to Ching-tsong, revived the courage of the Kitan; and, in 1035, war would have

been renewed, had not the emperor condescended to as shameful a treaty as that concluded by his father. Two years after, the Tartars demanded restitution of ten cities in the province of Pecheli, which had been taken by Ko-ghey founder of the 18th dynasty; upon which Jin-tsong engaged to pay them an annual tribute of 200,000 taels of silver, and 300,000 pieces of silk in lieu of these cities.

From this time, the Kitan remained in peaceable possession of their Chinese dominions till the year 1117. Whey-tsong, at that time emperor, being able neither to bear their ravages, nor by himself to put a stop to them, resolved upon a remedy which at last proved worse than the disease. This was to call in the Nu-che, Nyu-che, or Eastern Tartars, to destroy the kingdom of the Kitan. From this he was dissuaded by the king of Korea, and most of his own ministers; but, disregarding their salutary advice, he joined his forces to those of the Nu-che. The Kitan were then every where defeated; and at last reduced to such extremity, that those who remained were forced to leave their country, and fly to the mountains of the west.

Thus the empire of the Kitan was totally destroyed, but nothing to the advantage of the Chinese; for the Tartar general, elated with his conquest, gave the name of *Kin* to his new dominion, assumed the title of emperor, and began to think of aggrandizing himself and enlarging his empire. For this purpose, he immediately broke the treaties concluded with the Chinese emperor; and, invading the provinces of Pecheli and Shen-si, made himself master of the greater part of them. Whey-tsong, finding himself in danger of losing his dominions, made several advantageous proposals to the Tartar; who, seeming to comply with them, invited him to come and settle matters by a personal conference. The Chinese monarch complied: but, on his return, the terms agreed on seemed intolerable to his ministers; so that they told him the treaty could not subsist, and that the most cruel war was preferable to such an ignominious peace. The Kin monarch, being informed of all that passed, had recourse to arms, and took several cities. Whey-tsong was weak enough to go in person to hold a second conference; but, on his arrival, was immediately seized by the Tartar. He was kept prisoner under a strong guard during the remaining part of his life; and ended his days in 1126, in the desert of Shamo, having nominated his eldest son Kin-tsong to succeed him.

Kin-tsong began his reign with putting to death six ministers of state, who had betrayed his father into the hands of the Kin Tartars. The barbarians in the mean time pursued their conquests without opposition. They crossed the Whang-ho, or Yellow River, which an handful of troops might have prevented; and marching directly towards the imperial city, took and plundered it. Then seizing the emperor and his court, they carried them away captives: but many of the principal lords, and several of the ministers, preferring death to such an ignominious bondage, killed themselves. The Kin being informed by the empress *Meng* that she had been divorced, they left her behind. This proved the means of saving the empire; for

China. for by her wisdom and prudence she got the crown placed on the head of Kau-tsung, ninth son of the emperor Whey-tsung by his divorced empress.

17
Progress of
the Kin
checked.

Kau-tsung fixed his court at Nanking the capital of Kyang-nan; but soon after was obliged to remove it to Kang-chew in Che-kyang. He made several efforts to recover some of his provinces from the Kin, but without effect. Ili-tsung the Kin monarch, in the mean time, endeavoured to gain the esteem of his Chinese subjects by paying a regard to their learning and learned men, and honouring the memory of Confucius. Some time after, he advanced to Nanking, from whence Kau-tsung had retired, and took it: but, receiving advice that Yo-si, general of the Song, or southern Chinese, was advancing by long marches to the relief of that city, they set fire to the palace, and retired northward. However, Yo-si arrived time enough to fall upon their rear-guard, which suffered very much; and from this time the Kin never dared to cross the river Kyang. In a few years afterwards the Chinese emperor submitted to become tributary to the Kin, and concluded a peace with them upon very dishonourable terms. This submission, however, was of little avail: for, in 1163, the Tartars broke the peace; and, invading the southern province with a formidable army, took the city of Yang-chew. The king, having approached the river Kyang, near its mouth, where it is widest as well as most rapid, commanded his troops to cross it, threatening with his drawn sword to kill those who refused. On receiving such an unreasonable command, the whole army mutinied; and the king being killed in the beginning of the tumult, the army immediately retired.

18
They are
attacked by
Jenghiz-
khan and
the king of
Hya.

From this time to the year 1210, nothing remarkable occurs in the Chinese history; but this year, Jenghiz-khan, chief of the western Tartars, *Moguls*, or *Mungls*, quarrelled with Yong-tsi emperor of the Kin; and at the same time the king of Hya, disgusted at being refused assistance against Jenghiz-khan, threatened him with an invasion on the west side. Yong-tsi prepared for his defence; but in 1211, receiving news that Jenghiz-khan was advancing southward with his whole army, he was seized with fear, and made proposals of peace, which were rejected. In 1212, the Mogul generals forced the great wall; or, according to some writers, had one of the gates treacherously opened to them, to the north of Shanfi; and made incursions as far as Peking the capital of the Kin empire. At the same time the province of Lyau-tong was almost totally reduced by several Kitan lords who had joined Jenghiz-khan; several strong places were taken, and an army of 300,000 Kin defeated by the Moguls. In autumn they laid siege to the city of Tay-tong-fu; where, although the governor Hujaku fled, yet Jenghiz-khan met with considerable resistance. Having lost a vast number of men, and being himself wounded by an arrow, he was obliged to raise the siege and retire into Tartary; after which the Kin retook several cities. The next year, however, Jenghiz-khan re-entered China; retook the cities which the Kin had reduced the year before; and overthrew their armies in two bloody battles, in one of which the ground was strewed with dead bodies for upwards of four leagues.

19
Great wall
forced by
Jenghiz-
khan.

The same year Yong-tsi was slain by his general Hujaku; and Sun, a prince of the blood, advanced in his room. After this the Moguls, attacking the empire with four armies at once, laid waste the provinces of Shanfi, Honan, Pecheli, and Shantung. In 1214 Jenghiz-khan sat down before Peking; but instead of assaulting the city, offered terms of peace, which were accepted, and the Moguls retired into Tartary. After their departure, the emperor, leaving his son at Peking, removed his court to Pyen-lyang near Kay-sung-fu, the capital of Honan. At this Jenghiz-khan being offended, immediately sent troops to besiege Peking. The city held out to the fifth month of the year 1215, and then surrendered. At the same time the Moguls finished the conquest of Lyau-tong; and the Song refused to pay the usual tribute to the Kin.

20
Peking taken.

In 1216, Jenghiz-khan returned to pursue his conquests in the west of Asia, where he staid seven years; during which time his general Muhuli made great progress in China against the Kin emperor. He was greatly assisted by the motions of Ning-tsung emperor of the Song, or southern China; who, incensed by the frequent perfidies of the Kin, had declared war against them, and would hearken to no terms of peace, though very advantageous proposals were made. Notwithstanding this, however, in 1220, the Kin, exerting themselves, raised two great armies, one in Shenfi, and the other in Shang-ton. The former baffled the attempts of the Song and king of Hya, who had united against them; but the latter, though no fewer than 200,000, were entirely defeated by Muhuli. In 1221, that officer passed the Whang-ho, and died after conquering several cities.

21
Southern
Chinese de-
clared war
against the
Kin.

In 1224, the Kin emperor died; and was succeeded by his son Shew, who made peace with the king of Hya: but next year, that kingdom was entirely destroyed by Jenghiz-khan. In 1226, Oktay son to Jenghiz-Khan marched into Honan, and besieged Kay-sung-fu, capital of the Kin empire; but was obliged to withdraw into Shenfi, where he took several cities, and cut in pieces an army of 30,000 men. In 1227 Jenghiz-khan died, after having desired his sons to demand a passage for their army through the dominions of the Song, without which he said they could not easily vanquish the Kin.

22
Jenghiz-
khan de-
stroys the
kingdom of
Hya;

23
And dies.

After the death of that great conqueror, the war was carried on with various success; but though the Moguls took above 60 important posts in the province of Shenfi, they found it impossible to force Tong-quan, which it behoved them to do in order to penetrate effectually into Honan. In April 1231 they took the capital of Shenfi, and defeated the Kin army which came to its relief. Here one of the officers desired prince Toley to demand a passage from the Song through the country of Han-chong-fu. This proposal Toley communicated to his brother Oktay, who approved of it as being conformable to the dying advice of Jenghiz-khan. Hereupon Toley, having assembled all his forces, sent a messenger to the Song generals to demand a passage through their territories. This, however, they not only refused, but put the messenger to death; which so enraged Toley that he swore to make them repent of it, and was soon as good as his word. He decamped in August 1231; and having forced the passages, put to the sword the inhabitants of

Exploits of
Toley.

Wha.

China. Wha-yang and Fong-chew, two cities in the district of Han-chong-fu. Then having cut down rocks to fill up deep abysses, and made roads through places almost inaccessible, he came and besieged the city of Han-chong-fu itself. The miserable inhabitants fled to the mountains on his approach, and more than 100,000 of them perished. After this, Toley divided his forces, consisting of 30,000 horse, into two bodies. One of these went westward to Myen-chew: from thence, after opening the passages of the mountains, they arrived at the river Kyaling, which runs into the great Kyang. This they crossed on rafts made of the wood of demolished houses; and then, marching along its banks, seized many important posts. At last, having destroyed more than 140 cities, towns, or fortresses, they returned to the army. The second detachment seized an important post in the mountains, called *Tautong*, six or seven leagues to the eastward of Han-chong-fu. On the other side Oktay advanced, in October, towards Pu-chew a city of Shan-si; which being taken after a vigorous defence, he prepared to pass the Whang-ho. Toley, after surmounting incredible difficulties, arrived in December on the borders of Honan, and made a shew as if he designed to attack the capital of the Kin empire. On his first appearance in Honan through a passage so little suspected, every body was filled with terror and astonishment, so that he proceeded for some time without opposition. At last the emperor ordered his generals, Hota, Ilapua, and others, to march against the enemy. Toley boldly attacked them; but was obliged to retire, which he did in good order. Hota was for pursuing him, saying that the Mogul army did not exceed 30,000 men, and that they seemed not to have eaten any thing for two or three days. Ilapua, however, was of opinion that there was no occasion for being so hasty, as the Moguls were inclosed between the rivers Han and Whang-ho, so that they could not escape. This negligence they soon had occasion to repent of: for Toley, by a stratagem, made himself master of their heavy baggage; which accident obliged them to retire to Tang-chew. From thence they sent a messenger to acquaint the emperor that they had gained the battle, but concealed the loss of their baggage. This good news filled the court with joy; and the people who had retired into the capital for its defence, left it again, and went into the country: but, in a few days after, the vanguard of the Moguls, who had been sent by the emperor Oktay, appeared in the field, and carried off a great number of those that had quitted the city.

26
Capital of
the Kin em-
pire be-
sieged.

In January 1232, Oktay passing the Whang-ho, encamped in the district of Kay-fong-fu, capital of the Kin empire, and sent his general Suputay to besiege the city. At that time the place was near 30 miles in circumference: but having only 40,000 soldiers to defend it, as many more from the neighbouring cities, and 20,000 peasants, were ordered into it; while the emperor published an affecting declaration, animating the people to defend it to the last extremity. Oktay, having heard with joy of Toley's entrance into Honan, ordered him to send succours to Suputay. On the other hand, the Kin generals advanced with 150,000 men to relieve the city; but being obliged to divide their forces in order to avoid in part the great road

N^o 77.

which Toley had obstructed with trees, they were attacked by that prince at a disadvantage, and, after a faint resistance, defeated with great slaughter, and the loss of both their generals, one killed and the other taken. The emperor now ordered the army at Tong-quan and other fortified places to march to the relief of Kay-fong-fu. They assembled accordingly, to the number of 110,000 foot and 15,000 horse; and were followed by vast numbers of people who expected by their means to be protected from the enemy. But many of these troops having deserted, and the rest being enfeebled by the fatigues of their march, they dispersed on the approach of their pursuers, who killed all they found in the highways. After this the Moguls took Tong-quan and some other considerable posts; but were obliged to raise the sieges of Quey-te-fu and Loyang, by the bravery of the governors. Kyang-shin, governor of Loyang, had only 3 or 4000 soldiers under him, while his enemies were 30,000 strong. He placed his worst soldiers on the walls, putting himself at the head of 400 brave men; whom he ordered to go naked, and whom he led to all dangerous attacks. He invented engines to cast large stones, which required but few hands to play them, and aimed so true as to hit at 100 paces distance. When their arrows failed, he cut those shot by the enemy into four pieces; pointed them with pieces of brass coin; and discharged them from wooden tubes with as much force as bullets are from a musket. Thus he harassed the Moguls for three months so grievously, that they were obliged, notwithstanding their numbers, to abandon the enterprize.

Oktay, at last, notwithstanding his successes, resolved to return to Tartary; and offered the Kin emperor peace, provided he became tributary, and delivered up to him 27 families which he named. These offers were very agreeable to the emperor; but Suputay, taking no notice of the treaty, pushed on the siege of the capital with more vigour than ever. By the help of the Chinese slaves in his army, the Mogul general soon filled the ditch; but all his efforts seemed only to inspire the besieged with new vigour. The Moguls at that time made use of artillery, but were unable to make the least impression upon the city walls. They raised walls round those they besieged, which they fortified with ditches, towers, and battlements. They proceeded also to sap the walls of the city; but were very much annoyed by the artillery of the besieged, especially by their bombs, which sinking into the galleries, and bursting under ground, made great havock among the miners. For 16 days and nights the attacks continued without intermission; during which time an incredible number of men perished on both sides: at length, Suputay, finding that he could not take the city, withdrew his troops, under pretence of conferences being on foot. Soon after, the plague began in Kay-fong-fu; and raged with such violence, that, in 50 days, 900,000 biers were carried out, besides a vast multitude of the poorer sort who could not afford any.

In a short time, two unlucky accidents occasioned a renewal of the war; which now put an end to the empire of the Kin. Gan-yong, a young Mogul lord, having assumed the government of some cities in Kyang-nan, and killed the officer sent to take possession

China. sion of them, declared for the Kin. The emperor unwarily took Gan-yong into his service, and gave him the title of Prince. Upon this Oktay sent an envoy, attended by 30 other persons, to inquire into the affair; but the Kin officers killed them all, without being punished by the emperor. Suputay, having informed his master of all these proceedings, was ordered to continue the war in Honan. Shew-fu now commanded his officers to unite their troops for the defence of the capital; but before his orders could be obeyed, they were attacked and defeated, one after another, by the Moguls. This obliged him to raise soldiers from among the peasants, for whose subsistence the people were taxed $\frac{1}{5}$ of the rice they possessed. The city began now to be distressed for want of provisions; and as it was but in a bad posture of defence, the emperor marched with an army against the Moguls. His expedition proved unfortunate; for, sending part of his army to besiege a city called Why-chew, it was totally cut in pieces, and Suputay a second time sat down before the capital.

Siege of
Juning-fu.

33
Unhappy
fate of the
emperor.

On hearing this bad news, the emperor repassed the Whang-ho, and retired to Quey-te-fu. Here he had not been long before the capital was delivered up by treachery, and Suputay put all the males of the imperial race to death; but, by the express command of Oktay, spared the inhabitants, who are said to have amounted to 1,400,000 families. After this disaster the unhappy monarch left his troops at Quey-te-fu, and retired to Juning-fu, a city in the southern part of Honan, attended only by 400 persons. Here the distance of the Moguls made him think of living at ease; but while he flattered himself with these vain hopes, the enemy's army arrived before the city and invested it. The garrison were terrified at their approach; but were encouraged by the emperor, and his brave general Hu-sye-hu, to hold out to the last. As there were not in the city a sufficient number of men, the women, dressed in mens clothes, were employed to carry wood, stones, and other necessary materials to the walls. All their efforts, however, were ineffectual. They were reduced to such extremities, that for three months they fed on human flesh; killing the old and feeble, as well as many prisoners, for food. This being known to the Moguls, they made a general assault in January 1234. The attack continued from morning till night; but at last the assailants were repulsed. In this action, however, the Kin lost all their best officers; upon which the emperor resigned the crown to Cheng-lin a prince of the blood. Next morning, while the ceremony of investing the new emperor was performing, the enemy mounted the south walls, which were defended only by 200 men; and the south gate being at the same time abandoned, the whole army broke in. They were opposed, however, by Hu-sye-hu; who, with 1000 soldiers, continued to fight with amazing intrepidity. In the mean time Shew-fu, seeing every thing irreparably lost, lodged the seal of the empire in a house; and then causing sheaves of straw to be set round it, ordered it to be set on fire as soon as he was dead. After giving this order he hanged himself, and his commands were executed by his domestics. Hu-sye-hu, who still continued fighting with great bravery, no sooner heard of the tragical death of the emperor, than he drown-

VOL. IV. Part II.

ed himself in the river Ju; as did also 500 of his most resolute soldiers. The same day the new emperor, Cheng-lin, was slain in a tumult; and thus an end was put to the dominion of the Kin Tartars in China.

The empire of China was now to be shared between the Song, or southern Chinese, and the Moguls. It had been agreed upon, that the province of Honan should be delivered up to the Song as soon as the war was finished. But they, without waiting for the expiration of the term, or giving Oktay notice of their proceedings, introduced their troops into Kay-fong-fu, Lo-yang, and other considerable cities. On this the Mogul general resolved to attack them; and repassing the Whang-ho, cut in pieces part of the garrison of Lo-yang, while they were out in search of provisions. The garrison of Kay-fong-fu likewise abandoned that place; and the Song emperor degraded the officers who had been guilty of those irregularities, sending ambassadors to Oktay, at the same time, to desire a continuance of the peace. What Oktay's answer was we are not told, but the event showed that he was not well pleased; for, in 1235, he ordered his second son prince Kotovan, and his general Chahay, to attack the Song in Se-chwen, while others marched towards the borders of Kyang-nan.

In 1236, the Moguls made great progress in the province of Huquang, where they took several cities, and put vast numbers to the sword. This year they introduced paper or silk money, which had formerly been used by Chang-tsung, sixth emperor of the Kin. Prince Kotovan forced the passages into the district of Hang-chong-fu in the province of Shenfi, which he entered with an army of 500,000 men. Here a terrible battle was fought between the vast army of the Moguls and the Chinese troops, who had been driven from the passages they defended. The latter consisted only of 10,000 horse and foot, who were almost entirely cut off; and the Moguls lost such a number of men, that the blood is said to have run for two leagues together. After this victory the Moguls entered Sechwen, which they almost entirely reduced, committing such barbarities, that, in one city, 40,000 people chose rather to put an end to their own lives than submit to such cruel conquerors.

In 1237, the Moguls received a considerable check before the city of Gantong in Kyang-nan, the siege of which they were obliged to raise with loss. In 1238 they besieged Lu-chew, another city in the same province. They surrounded it with a rampart of earth and a double ditch; but the Chinese general ordered their intrenchments to be filled with immense quantities of herbs steeped in oil, and then set on fire, while he shot stones upon them from a tower seven stories high. At the same time a vigorous sally was made; and the Mogul army being thrown into the utmost disorder, were obliged finally to abandon the siege, and retire northwards.

In 1239, these barbarians were opposed by a general called Meng-kong, with great success; who, this and the following year, gained great honour by his exploits. While he lived, the Moguls were never able to make any considerable progress; but his death, in 1246, proved of the greatest detriment to the Chinese affairs: and soon after, the Tartars renewed the war with more vigour and success than ever. 1255, they re-entered the province of Se-chwen; but still met with vigorous opposition in this quarter, because the Chinese took care to have Se-chwen furnished with good troops and generals. Though they were always beaten, being greatly inferior in number to their enemies, yet they generally retook the cities the Moguls had reduced, as the latter were commonly obliged to withdraw for want of provisions and forage. In 1259 they undertook the siege of Ho-chew, a strong city to the west of Peking, defended by Vang-kyen, a very able officer, who commanded a numerous garrison. The siege continued from the month of February till August; during which time the Moguls lost an immense number of men. On the 10th of August they made a general assault in the night. They mounted the walls before the governor had intelligence; but were soon attacked by him with the utmost fury. The Mogul emperor, Meng-ko, himself came to the scalade; but his presence was not sufficient to overcome the valour of Vang-kyen. At the same time the scaling-ladders of the Moguls were blown down by a storm; upon which a terrible slaughter ensued, and amongst the rest fell the emperor himself. Upon this disaster the Mogul generals agreed to raise the siege, and retire towards Shen-si.

On the death of Meng-ko, Hupilay, or Kublay Khan, who succeeded him, laid siege to Vu-chang-fu, a city not far distant from the capital of the Song empire.

At this the emperor being greatly alarmed, distributed immense sums among his troops; and, having raised a formidable army, marched to the relief of Vu-chang-fu. Unfortunately the command of this army was committed to the care of Kya-tse-tau, a man without either courage or experience in war. He was besides very vain and vindictive in his temper; often using the best officers ill, and entirely overlooking their merit, which caused many of them to go over to the Moguls. The siege of Vu-chang-fu was commenced, and had continued a considerable time, when Kya-tse-tau, afraid of its being lost, and at the same time not daring to take any effectual step for its relief, made proposals of peace. A treaty was accordingly concluded, by which Kya-tse-tau engaged to pay an annual tribute of about L. 50,000 in silver, and as much in silk; acknowledging likewise the sovereignty of the Moguls over the Song empire. In consequence of this treaty, the Moguls retreated after the boundaries of the two empires had been fixed, and repassed the Kyang; but 170 of them having staid on the other side of the river, were put to death by Kya-tse-tau.

This wicked minister totally concealed from the emperor his having made such a shameful treaty with the Moguls; and the 170 soldiers massacred by his order, gave occasion to a report that the enemy had been defeated; so that the Song court believed that they had been compelled to retreat by the superior valour and wisdom of Kya-tse-tau. This proved the ruin of the empire; for, in 1260, the Mogul emperor sent Hauking to the Chinese court to execute the treaty according to the terms agreed on with Kya-tse-tau. The minister, dreading the arrival of this envoy, imprisoned him near Nanking; and took all possible care that neither Hupilay, nor Li-tsung the Chinese emperor, should ever hear any thing of him.

It was impossible such unparalleled conduct could

fail to produce a new war. Hupilay's courtiers incessantly pressed him to revenge himself on the Song for their treacherous behaviour; and he soon published a manifesto against them, which was followed by a renewal of hostilities in 1268. The Mogul army amounted to 300,000 men; but notwithstanding their numbers, little progress was made till the year 1271. Syan-yang and Fan-ching, cities in the province of Se-chew, had been besieged for a long time ineffectually; but this year an *Igur* lord advised Hupilay to send for several of those engineers out of the west, who knew how to cast stones of 150 pounds weight out of their engines, which made holes of seven or eight feet wide in the strongest walls. Two of these engineers were accordingly sent for; and after giving a specimen of their art before Hupilay, were sent to the army in 1272. In the beginning of 1273 they planted their engines against the city of Fan-ching, and presently made a breach in the walls. After a bloody conflict the suburbs were taken; and soon after the Moguls made themselves masters of the walls and gates of the city. Nevertheless, a Chinese officer, with only 100 soldiers, resolved to fight from street to street. This he did for a long time with the greatest obstinacy, killing vast numbers of the Moguls; and both parties are said to have been so much overcome with thirst, that they drank human blood to quench it. The Chinese set fire to the houses, that the great beams, falling down, might embarrass the way of their pursuers; but at last being quite wearied out, and filled with despair, they put an end to their own lives. After the taking of Fan-ching, all the materials which had served at the siege were transported to Seyen-yang. The two engineers posted themselves against a wooden retrenchment raised on the ramparts. This they quickly demolished; and the besieged were so intimidated by the noise and havoc made by the stones cast from these terrible engines, that they immediately surrendered.

In 1274, Pe-yen, an officer of great valour, and endowed with many other good qualities, was promoted to the command of the Mogul army. His first exploits were the taking of two strong cities; after which he passed the great river Ky-ang, defeated the Song army, and laid siege to Vu-chang-fu. This city was soon intimidated into a surrender; and Pe-yen, by restraining the barbarity of his soldiers, whom he would not allow to hurt any body, soon gained the hearts of the Chinese so much, that several cities surrendered to him on the first summons. In the meantime the treacherous Kya-tse-tau, who was sent to oppose Pe-yen, was not ashamed to propose peace on the terms he had formerly concluded with Hupilay; but these being rejected, he was obliged at length to come to an engagement. In this he was defeated, and Pe-yen continued his conquests with great rapidity. Having taken the city of Nanking, and some others, he marched towards Hang-chew-fu, the capital of the Song empire. Peace was now again proposed, but rejected by the Mogul general; and at last the empress was constrained to put herself, with her son, then an infant, into the hands of Pe-yen, who immediately sent them to Hupilay.

The submission of the empress did not yet put an end to the war. Many of the chief officers swore to do

submits.

China. do their utmost to rescue her from the hands of her enemies. In consequence of this resolution they distributed their money among the soldiers, and soon got together an army of 40,000 men. This army attacked the city where the young emperor Kong-tsong was lodged, but without success; after which, and several other vain attempts, they raised one of his brothers to the throne, who then took upon him the name of Twon-tsong. He was but nine years of age when he was raised to the imperial dignity, and enjoyed it but a very short time. In 1277 he was in great danger of perishing, by reason of the ship on board which he then was being cast away. The poor prince fell into the water, and was taken up half dead with the fright. A great part of his troops perished at that time, and he soon after made offers of submission to Hupilay. These, however, were not accepted; for, in 1278, the unhappy Twon-tsong was obliged to retire into a little desert island on the coast of Quang-tong, where he died in the 11th year of his age.

42
Dissolution
of the Song
empire.

Notwithstanding the progress of the Moguls, vast territories still remained to be subdued before they could become masters of all the Chinese empire. On the death of Twon-tsong, therefore, the mandarins raised to the throne his brother, named Te-ping, at that time but eight years of age. His army consisted of no fewer than 200,000 men; but being utterly void of discipline, and entirely ignorant of the art of war, they were defeated by 20,000 Mogul troops. Nor was the fleet more successful; for being put in confusion by that of the Moguls, and the emperor in danger of falling into their hands, one of the officers taking him on his shoulders, jumped with him into the sea, where they were both drowned. Most of the mandarins followed this example, as did also the empress and minister, all the ladies and maids of honour, and multitudes of others, insomuch that 100,000 people are thought to have perished on that day. Thus ended the Chinese race of emperors; and the Mogul dynasty, known by the name of *Ywen*, commenced.

43
Reign of
Hupilay.

Though no race of men that ever existed were more remarkable for cruelty and barbarity than the Moguls; yet it doth not appear that the emperors of the Ywen dynasty were in any respect worse than their predecessors. On the contrary, Hupilay, by the Chinese called *Shi-tsu*, found the way of reconciling the people to his government, and even of endearing himself to them so much, that the reign of his family is to this day styled by the Chinese *the wise government*. This he accomplished by keeping as close as possible to their ancient laws and customs, by his mild and just government, and by his regard for their learned men. He was indeed ashamed of the ignorance and barbarity of his Mogul subjects, when compared with the Chinese. The whole knowledge of the former was summed up in their skill in managing their arms and horses, being perfectly destitute of every art or science, or even of the knowledge of letters. In 1269, he had caused the Mogul characters to be contrived. In 1280, he caused some mathematicians search for the source of the river Whang-ho, which at that time was unknown to the Chinese themselves. In four months time they arrived in the country where it rises, and made a map of it, which

China. they presented to his majesty. The same year a treatise on astronomy was published by his order; and, in 1282, he ordered the learned men to repair from all parts of the empire to examine the state of literature, and take measures for its advancement.

At his first accession to the crown he fixed his residence at Tay-ywen-fu, the capital of Shen-si; but thought proper afterwards to remove it to Peking. Here, being informed that the barks which brought to court the tribute of the southern provinces, or carried on the trade of the empire, were obliged to come by sea, and often suffered shipwreck, he caused that celebrated canal to be made, which is at present one of the wonders of the Chinese empire, being 300 leagues in length. By this canal above 9000 imperial barks transport with ease, and at small expence, the tribute of grain, rice, silks, &c. which is annually paid to the court. In the third year of his reign Shi-tsu formed a design of reducing the islands of Japan, and the kingdoms of Tonkquin and Cochin-china. Both these enterprises ended unfortunately, but the first remarkably so; for of 100,000 persons employed in it, only four or five escaped with the melancholy news of the destruction of the rest, who all perished by shipwreck. Shi-tsu reigned 15 years, died in the 80th year of his age, and was succeeded by his grandson. The throne continued in the Ywen family till the year 1367, when Shun-ti, the last of that dynasty, was driven out by a Chinese named Chu. During this period the Tartars had become enervated by long prosperity; and the Chinese had been roused into valour by their subjection. Shun-ti, the reigning prince, was quite sunk in sloth and debauchery; and the empire, besides, was oppressed by a wicked minister named Ama. In June 1355, Chu, a Chinese of mean extraction, and head of a small party, set out from How-chew, passed the Kyang, and took Tay-ping. He then associated himself with some other malcontents, at the head of whom he reduced the town of Tu-chew, in Kyangnan. Soon after he made himself master of Nanking, having defeated the Moguls who came to its relief. In December 1356, he was able to raise 100,000 men, at the head of whom he took the city of U-chew, in the east borders of Quang-si; and here, assembling his generals, it was resolved neither to commit slaughters nor to plunder. The most formidable enemy he had to deal with was *Chen-yew-lyang*, styled "emperor of the Han." This man being grieved at the progress made by Chu, equipped a fleet, and raised a formidable army, in order to reduce Nan-chang-fu, a city of Kyang-si, which his antagonist had made himself master of. The governor, however, found means to inform Chu of his danger; upon which that chief caused a fleet to be fitted out at Nanking, in which he embarked 200,000 soldiers. As soon as Chen-yew-lyang was informed of his enemy's approach, he raised the siege of Nan-chang-fu, and gave orders for attacking Chu's naval force. An engagement ensued between a part of the fleets, in which Chu proved victorious; and next day, all the squadrons having joined in order to come to a general engagement, Chu gained a second victory, and burnt 100 of the enemy's vessels. A third and fourth engagement happened, in both which Chu gained the victory; and in

China.

44
The Moguls driven out.

45
Exploits of Chu.

China.

the last, Chen-yew-lyang himself was killed, his son taken prisoner, and his generals obliged to surrender themselves, with all their forces and vessels.

46

He is proclaimed king of U.

In January 1364, Chu's generals proposed to have him proclaimed emperor; but this he declined, and at first contented himself with the title of king of U. In February he made himself master of Vu-chang-fu, capital of Hu-quang; where, with his usual humanity, he relieved those in distress, encouraged the literati, and would allow his troops neither to plunder nor destroy. This wise conduct procured him an easy conquest both of Kyang-fi and Hu-quang. The Chinese submitted to him in crowds, and professed the greatest veneration and respect for his person and government.

47

Becomes emperor of China.

All this time Shun-ti, with an unaccountable negligence, never thought of exerting himself against Chu, but continued to employ his forces against the rebels who had taken up arms in various parts of the empire; so that Chu found himself in a condition to assume the title of emperor. This he chose to do at Nanking on the first day of the year 1368. After this his troops entered the province of Honan, which they presently reduced. In the third month, Chu, who had now taken the title of *Hong-vu*, or *Tay-tsu*, reduced the fortress of Tong-quan; after which his troops entered Pecheli from Honan on the one side, and Shan-tong on the other. Here his generals defeated and killed one of Shun-ti's officers; after which they took the city of Tong-chew, and then prepared to attack the capital, from which they were now but 12 miles distant. On their approach the emperor fled with all his family beyond the great wall, and thus put an end to the dynasty of Ywen. In 1370 he died, and was succeeded by his son, whom the successor of Hong-vu drove beyond the Kobi or Great Desert, which separates China from Tartary. They continued their incursions, however, for many years; nor did they cease their attempts till 1583, when vast numbers of them were cut in pieces by the Chinese troops.

48

Moguls driven beyond the desert.

The 21st dynasty of Chinese emperors, founded in 1368 by Chu, continued till the year 1644, when they were again expelled by the Tartars. The last Chinese emperor was named Whay-tsung, and ascended the throne in 1628. He was a great lover of the sciences, and a favourer of the Christians; though much addicted to the superstitions of the Bonzes. He found himself engaged in a war with the Tartars, and a number of rebels in different provinces. That he might more effectually suppress the latter, he resolved to make peace with the former; and for that end sent one of his generals, named Ywen, into Tartary, at the head of an army, with full power to negotiate a peace; but that traitor made one upon such shameful terms, that the emperor refused to ratify it. Ywen, in order to oblige his master to comply with the terms made by himself, poisoned his best and most faithful general, named *Mau-ven-long*; and then desired the Tartars to march directly to Peking, by a road different from that which he took with his army. This they accordingly did, and laid siege to the capital. Ywen was ordered to come to its relief; but, on his arrival, was put to the torture and strangled; of which the Tartars were no sooner informed, than they raised the siege, and returned to their own country. In 1636,

49

China again conquered by the Tartars

the rebels above-mentioned composed four great armies, commanded by as many generals; which, however, were soon reduced to two, commanded by Li and Chang. These agreed to divide the empire between them; Chang taking the western provinces, and Li the eastern ones. The latter seized on part of Shen-fi, and then of Honan, whose capital, named Kay-fong-fu, he laid siege to, but was repulsed with loss. He renewed it six months after, but without success; the besieged choosing rather to feed on human flesh than surrender. The Imperial forces coming soon after to its assistance, the general made no doubt of being able to destroy the rebels at once, by breaking down the banks of the Yellow River; but unfortunately the rebels escaped to the mountains, while the city was quite overflowed, and 300,000 of the inhabitants perished.

After this disaster, Li marched into the provinces of Shen-fi and Honan; where he put to death all the mandarins, exacted great sums from the officers in place, and showed no favour to any but the populace, whom he freed from all taxes: by this means he drew so many to his interest, that he thought himself strong enough to assume the title of emperor. He next advanced towards the capital, which, though well garrisoned, was divided into factions. Li had taken care to introduce before-hand a number of his men in disguise; and by these the gates were opened to him the third day after his arrival. He entered the city in triumph at the head of 300,000 men; whilst the emperor kept himself shut up in his palace, busied only with his superstitions. It was not long, however, before he found himself betrayed: and, under the greatest consternation, made an effort to get out of the palace, attended by about 600 of his guards. He was still more surprised to see himself treacherously abandoned by them, and deprived of all hopes of escaping the insults of his subjects. Upon this, preferring death to the disgrace of falling alive into their hands, he immediately retired with his empress, whom he tenderly loved, and the princess her daughter, into a private part of the garden. His grief was so great that he was not able to utter a word; but she soon understood his meaning, and, after a few silent embraces, hanged herself on a tree in a silken string. Her husband staid only to write these words on the border of his vest: "I have been basely deserted by my subjects; do what you will with me, but spare my people." He then cut off the young princess's head with one stroke of his scymitar, and hanged himself on another tree, in the 17th year of his reign, and 36th of his age. His prime minister, queens, and eunuchs, followed his example; and thus ended the Chinese monarchy, to give place to that of the Tartars, which hath continued ever since.

It was some time before the body of the unfortunate monarch was found. At last it was brought before the rebel Li, and by him used with the utmost indignity; after which he caused two of Whey-tsung's sons, and all his ministers, to be beheaded; but his eldest son happily escaped by flight. The whole empire submitted peaceably to the usurper, except prince U-fan-ghey, who commanded the imperial forces in the province of Lyau-tong. This brave prince, finding himself unable to cope with the usurper, invited the Tartars.

China.

Unhappy fate of the emperor and his family.

China.

Tartars to his assistance, and T'fong-te their king immediately joined him with an army of 80,000 men. Upon this the usurper marched directly to Peking; but not thinking himself safe there, plundered and burnt the palace, and then fled with the immense treasure he had got. What became of him afterwards we are not told; but the young Tartar monarch was immediately declared emperor of China, his father T'fong-te having died almost as soon as he set his foot in that empire.

The new emperor, named *Shun-chi*, or *Xun-chi*, began his reign with rewarding U-fan-ghey, by conferring upon him the title of King; and assigned him the city of Si-gnan-fu, capital of Shen-si, for his residence. This, however, did not hinder U-fan-ghey from repenting of his error in calling in the Tartars, or, as he himself used to phrase it, "in sending for lions to drive away dogs." In 1674, he formed a very strong alliance against them, and had probably prevailed if his allies had been faithful; but they treacherously deserted him one after another: which so affected him, that he died soon after. In 1681 Hong-wha, son to U-fan-ghey, who continued his efforts against the Tartars, was reduced to such straits that he put an end to his own life.

During this space, there had been some resistance made to the Tartars in many of the provinces. Two princes of Chinese extraction had at different times been proclaimed emperors; but both of them were overcome and put to death. In 1682, the whole 15 provinces were so effectually subdued, that the emperor Kang-hi, successor to Shun-chi, determined to visit his native dominions of Tartary. He was accompanied by an army of 70,000 men, and continued for some months taking the diversion of hunting. This he continued to do for some years; and in his journeys took father Verbeest along with him; by which means we have a better description of these countries than could possibly have been otherwise obtained. This prince was a great encourager of learning and of the Christian religion; in favour of which last he published a decree, dated in 1692. In 1716, however, he revived some obsolete laws against the Christians; nor could the Jesuits with all their art preserve the footing they had got in China. The causes of this alteration in his resolution are, by the missionaries, said to have been the slanders of the mandarins; but, from the known character of the Jesuits, it will be readily believed, that there was something more at bottom. This emperor died in 1722, and was succeeded by his son Yon-ching; who not only gave no encouragement to the missionaries, but persecuted all Christians of whatever denomination, not excepting even those of the imperial race. At the beginning of his reign he banished all the Jesuits into the city of Canton, and in 1732 they were banished from thence into Ma-kau, a little island inhabited by the Portuguese, but subject to China. He died in 1736; but though the Jesuits entertained great hopes from his successor, we have not heard that they have yet met with any success.

Thus we have given an account of the most memorable transactions recorded in the Chinese history. It now remains only to describe the present state of the empire and its inhabitants, according to the best and latest accounts.

The climate as well as the soil of this extensive empire is very different in different parts; severe cold being often felt in the northern provinces, while the inhabitants of the southern ones are scarce able to bear the heat. In general, however, the air is accounted wholesome, and the inhabitants live to a great age.—

The northern and western provinces have many mountains, which in the latter are cultivated, but in the north are barren, rocky, and incapable of improvement. On the mountains of Chenfi, Honan, Canton, and Fokien, are many forests, abounding with tall, straight trees, of different kinds, fit for building, and particularly adapted for masts and ship-timber. These are used by the emperor in his private buildings; and from these forests enormous trunks are sometimes transported to the distance of more than 300 leagues. Other mountains contain quicksilver, iron, tin, copper, gold, and silver. Formerly these last were not allowed to be opened, lest the people should thereby be induced to neglect the natural riches of the soil; and it is certain, that, in the 15th century, the emperor caused a mine of precious stones to be shut, which had been opened by a private person. Of late, however, the Chinese are less scrupulous, and a great trade in gold is carried on by them. Many extravagant fables are told by the Chinese of their mountains, particularly of one in Chenfi which throws out flames, and produces violent tempests, whenever any one beats a drum or plays on a musical instrument near it.—In the province of Fokien is a mountain, the whole of which is an idol, or statue of the god Fo. This natural colossus, for it appears not to have been the work of art, is of such an enormous size, that each of its eyes is several miles in circumference, and its nose extends some leagues.

China has several large lakes; the principal one is that named Poyang-hou, in the province of Kiang-si. It is formed by the confluence of four large rivers, extends near 100 leagues in length; and, like the sea, its waters are raised into tempestuous waves. The empire is watered by an immense number of rivers of different sizes, of which two are particularly celebrated, viz. the *Yang-tse-kiang*, or *son of the sea*, and *Hoang-ho*, or the *yellow river*. The former rises in the province of Yun-nan, and passing through Hou-quang and Kiang-nan, falls into the eastern ocean, after a course of 1200 miles, opposite to the island of T'fon-ming, which is formed by the sand accumulated at its mouth. This river is of immense size, being half a league broad at Nanking, which is near 100 miles from its mouth. The navigation is dangerous, so that great numbers of vessels are lost on it. It runs with a rapid current, forming several islands in its course, which are again carried off and new ones formed in different places, when the river is swelled by the torrents from the mountains. These islands, while they remain, are very useful; producing great quantities of reeds ten or twelve feet high, which are used in all the neighbouring countries for fuel. The Hoang-ho, or yellow river, has its name from the yellow colour given it by the clay and sand washed down in the time of rain. It rises in the mountains which border the province of Te-tchuen on the west, and after a course of near 600 leagues, discharges itself into the eastern sea not far from the mouth of the Kiang. It is very broad and rapid, but so shallow that it is scarce navigable.

gable. It is very liable to inundations, often overflowing its banks, and destroying whole villages. For this reason it has been found necessary to confine it in several places by long and strong dykes; which yet do not entirely answer the purpose. The people of Honan, therefore, whose land is exceedingly low, have surrounded most of their cities with strong ramparts of earth faced with turf, at the distance of three furlongs.

55
Canals.

The Chinese have been at great pains to turn their lakes and rivers to the advantage of commerce, by promoting an inland navigation. One of their principal works for this purpose, is the celebrated canal reaching from Canton to Peking, and forming a communication between the southern and northern provinces. This canal extends through no less a space than 600 leagues; but its navigation is interrupted in one place by a mountain, where passengers are obliged to travel 10 or 12 leagues over land. A number of other canals are met with in this and other provinces; most of which have been executed by the industry of the inhabitants of different cities and towns, in order to promote their communication with the various parts of the empire. M. Grosier remarks, that, in these works, the Chinese have "surmounted obstacles that perhaps would have discouraged any other people; such, for example, is part of a canal which conducts from *Chao-king* to *Ning-po*." Near these cities there are two canals, the waters of which do not communicate, and which differ ten or twelve feet in their level. To render this place passable for boats, the Chinese have constructed a double glacis of large stones, or rather two inclined planes, which unite in an acute angle at their upper extremity, and extend on each side to the surface of the water. If the bark is in the lower canal, they push it up the plane of the first glacis by means of several capstans, until it is raised to the angle, when by its own weight it glides down the second glacis, and precipitates itself into the water of the higher canal with the velocity of an arrow. It is astonishing that these barks, which are generally very long and heavily laden, never burst asunder when they are balanced on this acute angle; however, we never hear of any accident of this kind happening in the passage. It is true, they take the precaution of using for their keels a kind of wood which is exceedingly hard, and proper for resisting the violence of such an effort.

56
Remark-
able river,
which part-
ly sinks un-
der ground.

The following remarkable phenomenon in a Chinese river is related by Father *le Couteux*, a French missionary. "Some leagues above the village *Che-pai* (says he), the river becomes considerably smaller, although none of its waters flow into any other channel; and, eight or nine leagues below, it resumes its former breadth, without receiving any additional supply, excepting what it gets from a few small rivulets, which are almost dry during the greater part of the year. Opposite to *Che-pai* it is so much diminished, that, excepting one channel, which is not very broad, I have passed and repassed it several times by the help of a common pole. I was always surprised to find this river so narrow and shallow in that place; but I never thought of inquiring into the cause of it, until the loss of a bark belonging to a Christian family afforded me an opportunity. In that place where the river diminishes almost of a sudden, it flows with great impetuosity; and where it resumes its former breadth it is equally

China.

rapid. At the sixth moon, when the water was high and the wind strong, the bark I have mentioned arriving above *Che-pai*, was driven on a sand-bank; for between these two places the river is full of moveable sands, which are continually shifting their situation. The master of the boat dropped his anchor until the wind should abate, and permit him to continue his voyage; but a violent vortex of moveable sand, which was cast up from the bottom of the river, laid the bark on its side; a second vortex succeeded; then a third; and afterwards a fourth, which shattered the bark to pieces. When I arrived at the place where this bark had been lost, the weather was mild and serene; I perceived eddies in the current every where around; which absorbed, and carried to the bottom of the river whatever floated on the surface; and I observed, at the same time, that the sand was thrown violently up with a vortical motion. Above these eddies the water was rapid, but without any fall; and in the place below, where the river resumes its usual course, no eddies are to be seen, but the sand is thrown up in the same violent manner; and in some places there are water-falls, and a kind of small islands scattered at some distance from one another. These islands which appear above the surface of the water, are not solid earth, but consist of branches of trees, roots, and herbs collected together. I was told that these boughs rose up from the water, and that no one knew the place from whence they came. I was informed, that these masses, which were 40 or 50 feet in extent on that side on which we passed, were immovable, and fixed in the bottom of the river; that it was dangerous to approach them, because the water formed whirlpools every where around them; that, however, when the river was very low, the fishermen sometimes ventured to collect the bushes that floated on its surface, and which they used for fuel. I am of opinion, that, at the place of the river which is above *Che-pai*, the water falls into deep pits, from whence it forces up the sand with that vortical motion; and that it flows under-ground to the other place, eight or nine leagues below, where it carries with it all the boughs, weeds, and roots, which it washes down in its course, and thus forms those islands which appear above its surface. We know there are some rivers that lose themselves entirely, or in part, in the bowels of the earth, and which afterwards arise in some other place; but I believe there never was one known to lose part of its water below its own channel, and again to recover it at the distance of some leagues."

It has already been said, that China is, in general, a fertile country; and indeed all travellers agree in this respect, and make encomiums on the extent and beauty of its plains. So careful are the husbandmen of this empire to lose none of their ground, that neither inclosure, hedge, nor ditch, nay, scarce a single tree, are ever to be met with. In several places the land yields two crops a-year; and even in the interval between the harvests, the people sow several kinds of pulse and small grain. The plains of the northern provinces yield wheat; those of the southern, rice, because the country is low and covered with water. Notwithstanding all this fertility, however, the inhabitants are much more frequently afflicted with famine than those of the European nations, though the countries of Europe produce much less than China. For this

57

Why China
is subject to
famines,
notwith-
standing its
fertility.

China. this two causes are assigned. 1. The destruction of the rising crops by drought, hail, inundations, locusts, &c. in which case China cannot like the European countries be supplied by importation. This is evident by considering how it is situated with regard to other nations. On the north are the Mogul Tartars, a lazy and indolent race, who subsist principally on the flesh of their flocks; sowing only a little millet for their own use. The province of Leatong, which lies to the north-east, is indeed extremely fertile, but too far distant from the capital and centre of the empire to supply it with provisions; and besides, all carriage is impracticable but in the winter, when great quantities of game, and fish, preserved in ice, are sent thither. No corn is brought from Corea to China; and, though the Japan islands are only three or four days sailing from the Chinese provinces of Kiang-nan and Che-kyang, yet no attempt was ever made to obtain provisions from thence, whether it be, that the Japanese have nothing to spare, or on account of the insults offered by these islanders to foreign merchants. Formosa lies opposite to the province of Fo-kien; but so far is that island from being able to supply any thing, that in a time of scarcity it requires a supply from China itself. The province of Canton is also bounded by the sea, and has nothing on the south but islands and remote countries. One year, when rice was exceedingly scarce there, the emperor sent for F. Parranin, a Jesuit missionary, and asked him if the city of Macao could not furnish Canton with rice until the supply he had ordered from other provinces should arrive; but was informed that Macao had neither rice, corn, fruits, herbs, nor flocks; and that it generally got from China what was necessary for its subsistence.—The only method, therefore, the Chinese can take to guard against famines arising from these causes, is to erect granaries and public magazines in every province and most of the principal cities of the empire. This has at all times been a principal object of care to the public ministers; but though this mode of relief still takes place in theory, so many ceremonies are to be gone through before any supply can be drawn from those public repositories, that it seldom arrives seasonably at the places where it is wanted; and thus numbers of unhappy wretches perish for want. 2. Another cause of the scarcity of grain in this empire, is the prodigious consumpt of it in the composition of wines, and a spirituous liquor called *rack*. But though government is well apprized that this is one of the principal sources of famine throughout the empire, it never employed means sufficient to prevent it. Proclamations indeed have frequently been issued, prohibiting the distillation of rack; and the appointed officers will visit the still-houses and destroy the furnaces if nothing is given them; but on slipping some money into their hands, they shut their eyes, and go somewhere else to receive another bribe. When the mandarin himself goes about, however, these distillers do not escape quite so easily, the workmen being whipped and imprisoned, after which they are obliged to carry a kind of collar called the *Cangue**; the masters are likewise obliged to change their habitations and conceal themselves for a short time, after which they generally resume their operations. It is impossible, how-

* See below
No. 74.

ever, that any method of this kind can prove effectual in suppressing these manufactories while the liquors themselves are allowed to be sold publicly; and against this there is no law throughout the empire. Our author, however, justly observes, that in case of a prohibition of this kind, the grandees would be obliged to deny themselves the use of these luxuries, which would be too great a sacrifice for the good of the empire.

The population of China is so great, in comparison with that of the European countries, that the accounts of it have generally been treated as fabulous by the western nations; but by an accurate investigation of some Chinese records concerning the number of persons liable to taxation throughout the empire, M. Grofier has showed that it cannot be less than 200 millions. For this extraordinary population he assigns the following causes. 1. The strict observance of filial duty throughout the empire, and the prerogatives of fraternity, which make a son the most valuable property of a father. 2. The infamy attached to the memory of those who die without children. 3. The universal custom by which the marriage of children becomes the principal concern of the parents. 4. The honours bestowed by the state on those widows who do not marry a second time. 5. Frequent adoptions, which prevent families from becoming extinct. 6. The return of wealth to its original stock by the disinheriting of daughters. 7. The retirement of wives, which renders them more complaisant to their husbands, saves them from a number of accidents when big with child, and constrains them to employ themselves in the care of their children. 8. The marriage of soldiers. 9. The fixed state of taxes; which being always laid upon lands, never fall but indirectly on the trader and mechanic. 10. The small number of sailors and travellers. 11. To these may be added the great number of people who reside in China only by intervals; the profound peace which the empire enjoys; the frugal and laborious manner in which the great live; the little attention that is paid to the vain and ridiculous prejudice of marrying below one's rank; the ancient policy of giving distinction to men and not to families; by attaching nobility only to employments and talents, without suffering it to become hereditary. And, 12. lastly, A decency of public manners, and a total ignorance of scandalous intrigues and gallantry.

The government of China, according to the Abbe Grofier, is purely patriarchal. The emperor is more unlimited in his authority than any other potentate on earth; no sentence of death, pronounced by any of the tribunals, can be executed without his consent, and every verdict in civil affairs is subject to be revised by him; nor can any determination be of force until it has been confirmed by the emperor: and, on the contrary, whatever sentence he passes is executed without delay; his edicts are respected throughout the empire as if they came from a divinity; he alone has the disposal of all offices, nor is there any such thing as the purchase of places in China; merit, real or supposed, raises to an office, and rank is attached to it only. Even the succession to the throne is not altogether hereditary. The emperor of China has a power of choosing his own successor without consulting any of

China.

peror.

China

of his nobility; and can select one not only from among his own children, but even from the body of his people; and there have been several instances of his making use of this right: and he has even a power of altering the succession after it has once been fixed, in case the person pitched upon does not behave towards him with proper respect. The emperor can also prevent the princes of the blood from exercising the title, with which, according to the constitution of the empire, they are invested. They may indeed, notwithstanding this, possess their hereditary dignity; in which case they are allowed a revenue proportioned to their high birth, as well as a palace, officers, and a court; but they have neither influence nor power, and their authority is lower than that of the meanest mandarin.

60
Mandarins
of different
classes.

The mandarins are of two classes, viz. those of letters, and the inferior sort, styled mandarins of arms. The latter by no means enjoy the same consideration with the former sort; indeed in China the literati are highly honoured, and to their influence M. Grosier supposes that we may in a great measure ascribe the mildness and equity of the government; though he thinks that the balance may incline rather too much in their favour. Several degrees, answering to those of bachelor, licentiate, and doctor, must be passed through before one can attain to the dignity of a mandarin of letters; though sometimes, by the favour of the emperor, it is conferred on those who have attained only the two first degrees: but even the persons who have gone through all the three, enjoy at first only the government of a city of the second or third class. When several vacancies happen in the government of cities, the emperor invites to court a corresponding number of the literati, whose names are written down in a list. The names of the vacant governments are then put into a box, raised so high that the candidates are able only to reach it with their hands; after which they draw in their turns, and each is appointed governor of the city whose name he has drawn.

There are eight orders of these mandarins in China. 1. The *calao*, from whom are chosen the ministers of state, the presidents of the supreme courts, and all the superior officers among the militia. The chief of this order presides also in the emperor's council, and enjoys a great share of his confidence. 2. The *te-hiofe*, or man of acknowledged ability, is a title bestowed upon every mandarin of the second rank; and from these are selected the viceroys and presidents of the supreme council in the different provinces. 3. The *tchong-tchueo*, or school of mandarins, act as secretaries to the emperor. 4. *T-tchuen-tao*. These keep in repair the harbours, royal lodging-houses, and barks, which belong to the emperor, unless particularly engaged in some other office by his order. 5. The *ping-pi-tao* have the inspection of the troops. 6. The *tun-tien-hao* have the care of the high-ways. 7. The *ho-tao* superintend the rivers. 8. The *hai-tao* inspect the sea-coasts.

Thus the whole administration of the Chinese empire is intrusted to the mandarins of letters; and the homage paid by the common people to every mandarin in office, almost equals that paid to the emperor himself. This indeed flows from the nature of their

N^o 77.

2

government. In China it is a received opinion that the emperor is the father of the whole empire; that the governor of a province is the father of that province; and that the mandarin who is governor of a city is also the father of that city. This idea is productive of the highest respect and submission, which is not at all lessened by their great number; for though the mandarins of letters amount to more than 14,000, the same respect is paid to every one of them.

The mandarins of arms are never indulged with any share in the government of the state; however, to attain to this dignity, it is also necessary to pass through the degrees of bachelor, licentiate, and doctor of arms. The accomplishments necessary for a mandarin of arms are, strength of body, with ability and readiness in performing the various military exercises, and comprehending the orders requisite for the profession of arms: an examination on these subjects must be undergone before the candidate can attain the wished-for dignity.

The mandarins of arms have tribunals, the members of which are selected from among their chiefs; and among these they reckon princes, counts, and dukes; for all these dignities, or something equivalent to them, are met with in China. The principal of these tribunals is held at Peking, and consists of five classes. 1. The mandarins of the rear-guard, called *heou-fou*. 2. Of the left wing, or *tfa-fou*. 3. Of the right wing, or *yeou-feou*. 4. Of the advanced main-guard, or *te-hong-fou*. 5. Of the advanced guard, or *tshien-fou*. These five tribunals are subordinate to one named *iong-tching-fou*; the president of which is one of the great lords of the empire, whose authority extends over all the military men in the empire. By his high dignity he could render himself formidable even to the emperor; but to prevent this inconvenience, he has for his assessor a mandarin of letters, who enjoys the title and exercises the function of superintendant of arms. He must also take the advice of two inspectors who are named by the emperor; and when these four have agreed upon any measure, their resolution must still be submitted to the revial of an higher court named *Ping-pou*, which is entirely of a civil nature. The chief of these mandarins is a general of course, whose powers are equivalent to those of our commanders in chief; and below him are other mandarins who act as subordinate officers.

These two classes of mandarins compose what is called the nobility of China; but as we have already hinted, their office is not hereditary; the emperor alone continues or confers it. They have the privilege of remonstrating to the emperor, either as individuals or in a body, upon any part of his conduct which appears contrary to the interests of the empire. These remonstrances are seldom ill received, though the sovereign complies with them only when he himself thinks proper. The number of literary mandarins in China is computed at upwards of 14,000; and those of arms at 18,000; the former, however, are considered as the principal body in the empire; and this preference is thought to damp the military ardour of the nation in general, and to be one cause of that weakness in war for which the Chinese are remarkable.

The armies of this empire are proportioned to its vast extent and population; being computed in time of force.

China.

61
Tribunal of
the mandarin
of arms.

62

of

China. of peace at more than 700,000. Their pay amounts to about twopence half-penny and a measure of rice per day, though some of them have double pay, and the pay of a horseman is double that of a foot-soldier; the emperor furnishes a horse, and the horseman receives two measures of small beans for his daily subsistence; the arrears of the army being punctually paid up every three months.

The arms of a horseman are, a helmet, cuirass, lance, and sabre; those of a foot-soldier are a pike and sabre; some have fuses, and others bows and arrows. All these are carefully inspected at every review; and if any of them are found in the least rusted, or otherwise in bad condition, the possessor is instantly punished; if a Chinese, with 30 or 40 blows of a stick; or, if a Tartar, with as many lashes.

63 Use of fire-arms lost and revived. Though the use of gun-powder is certainly very ancient in China, it appears to have been afterwards totally lost, at least fire-arms seem to have been almost entirely unknown some centuries ago. Three or four cannon were to be seen at that time about the gates of Nanking; but not a single person in China knew how to make use of them; so that, in 1621, when the city of Macao made a present of three pieces of artillery to the emperor, it was found necessary also to send three men to load them. The utility of these weapons was quickly perceived by the execution which the three cannon did against the Tartars, at that time advanced as far as the great wall. When the invaders threatened to return, the mandarins of arms gave it as their opinion, that cannons were the best arms they could make use of against them. They were then taught the art of casting cannon by F. Adam Schaal and Verbiest, two Jesuit missionaries, and their artillery was increased to the number of 320 pieces; at the same time that they were instructed in the method of fortifying towns, and constructing fortresses and other buildings according to the rules of modern architecture.

The best soldiers in China are procured from the three northern provinces, the others being seldom called forth, but allowed to remain at peace with their families; indeed there is not often occasion for exerting their military talents, unless it be in the quelling of an insurrection, when a mandarin or governor usually accompanies them. They march in a very tumultuous manner, but want neither skill nor agility in performing their different evolutions. They, in general, handle a sabre well, and shoot very dexterously with bows and arrows. There are in China more than 2000 places of arms; and through the different provinces there are dispersed about 3000 towers or castles, all of them defended by garrisons. Soldiers continually mount guard there; and on the first appearance of tumult, the nearest centinel makes a signal from the top of the tower, by hoisting a flag in the day time, or lighting a torch in the night; when the neighbouring garrisons immediately repair to the place where their presence is necessary.

64 Account of the great wall.

The principal defence of the empire against a foreign enemy is the great wall which separates China from Tartary, extending more than 1500 miles in length, and of such thickness that six horsemen may easily ride abreast upon it. It is flanked with towers two bow-shots distant from one another; and it is said

Vol. IV. Part II.

that a third of the able bodied men in the empire were employed in constructing it. The workmen were ordered, under pain of death, to place the materials so closely, that not the least entrance might be afforded for any instrument of iron; and thus the work was constructed with such solidity, that it is still almost entire, though 2000 years have elapsed since it was constructed. This extraordinary work is carried on not only through the low lands and valleys, but over hills and mountains; the height of one of which was computed by F. Verbiest at 1236 feet above the level of the spot where he stood. According to F. Martini it begins at the gulf of Lea-tong, and reaches to the mountains near the city of Kin on the yellow river; between which places it meets with no interruption except to the north of the city of Suen in the province of Pecheli, where it is interrupted by a ridge of hideous and inaccessible mountains, to which it is closely united. It is likewise interrupted by the river Hoang-ho; but for others of an inferior size, arches have been constructed, through which the water passes freely. Mr Bell informs us, that it is carried across rivers, and over the tops of the highest hills, without the least interruption, keeping nearly along that circular range of barren rocks which incloses the country; and, after running about 1200 miles, ends in impassable mountains and sandy deserts. The foundation consists of large blocks of stone laid in mortar; but all the rest is of brick. The whole is so strong and well built, that it scarcely needs any repairs; and, in the dry climate in which it stands, may remain in the same condition for many ages. When carried over steep rocks, where no horse can pass, it is about 15 or 20 feet high; but when running through a valley, or crossing a river, it is about 30 feet high, with square towers and embrasures at equal distances. The top is flat, and paved with cut stone; and where it rises over a rock or eminence, there is an ascent made by an easy stone-stair. "This wall (our author adds) was begun and completely finished in the short space of five years; and it is reported, that the labourers stood so close for many miles, that they could hand the materials from one to another. This seems the more probable, as the rugged rocks among which it is built must have prevented all use of carriages; and neither clay for making bricks, nor any kind of cement, are to be found among them."

The whole civil government of China is managed 65 by the following courts. 1. The emperor's grand Courts by which the council, composed of all the ministers of state, presidents and assessors of the six sovereign courts, and of civil government three others, to be afterwards mentioned. This is never assembled but on affairs of the greatest importance; the emperor's private council being substituted to it in all cases of smaller moment. 2. The chief of the other courts furnishes mandarins for the different provinces, watches over their conduct, and keeps a journal of their transactions, and informs the emperor of them, who rewards or punishes according to the report he gets.

This second tribunal, which may be called a kind of civil inquisition, is subdivided into four others; the first entrusted with the care of selecting those who, on account of their learning or other good properties, are capable of filling the offices of government; the second

4 P

appointed

China.

China.

appointed to take care of the conduct of the mandarins; the third affixing the seals to the different public acts, giving the seals to mandarins, and examining those of the different dispatches; while the fourth enquires into the merit of the grandees of the empire, not excepting the princes of the imperial blood themselves. The principal sovereign court to which these four last are subordinate is called *Lii-pou*.

2. *Hou-pou*, or the grand treasurer, superintends all the finances of the state; is the guardian and protector of the treasures and dominions of the emperor, keeping an account of his revenues, &c. superintending the management and coining of money; the public magazines, custom-houses; and, lastly, keeping an exact register of all the families in the empire. To assist this court, 14 others are appointed throughout the different provinces of the empire.

3. *Li-pou*, or the court of ceremonies. "It is an undoubted fact (says M. Grosier), that ceremonies form, in part, the base of the Chinese government. This tribunal therefore takes care to support them, and enforce their observance; it inspects also the arts and sciences. It is consulted by the emperor when he designs to confer particular honours; takes care of the annual sacrifices offered up by him, and even regulates the entertainments which he gives either to strangers or to his own subjects. It also receives and entertains foreign ambassadors, and preserves tranquillity among the different religious sects in the empire. It is assisted by four inferior tribunals.

4. *Ping-pou*, or the tribunal of arms, comprehends in its jurisdiction the whole militia of the empire; inspecting also the fortresses, magazines, arsenals, and store-houses of every kind, as well as the manufactories of arms both offensive and defensive; examining and appointing officers of every rank. It is composed entirely of mandarins of letters; and the four tribunals depending upon it consist also of literati."

5. The *hong-pou* is the criminal bench for the whole empire, and is assisted by 14 subordinate tribunals.

6. The *cong-pou*, or tribunal of public works, surveys and keeps in repair the emperor's palaces, as well as those of the princes and viceroys, and the buildings where the tribunals are held, with the temples, tombs of the sovereigns, and all public monuments. It has besides the superintendence of the streets, public highways, bridges, lakes, rivers, and every thing relating either to internal or foreign navigation. Four inferior tribunals assist in the discharge of these duties; the first drawing the plans of public works; the second directing the work-shops in the different cities of the empire; the third surveying the causeways, roads, bridges, canals, &c.; and the fourth taking care of the emperor's palaces, gardens, and orchards, and receiving their produce.

66

Partiality
of govern-
ment to-
wards the
Chinese.

All these tribunals are composed, one half of Chinese, and the other of Tartars; and one of the presidents of each superior tribunal is always a Tartar born. None of the courts above described, however, has absolute authority even in its own jurisdiction; nor can its decisions be carried into execution without the concurrence of another tribunal, and sometimes of several others. The fourth tribunal, for instance, has indeed under its jurisdiction the whole troops of the empire; but the payment of them is entrusted with

the second, while the sixth has the care of the arms, tents, chariots, barks, and stores necessary for military operations; so that nothing relative to these can be put in execution without the concurrence of all the three tribunals.

China.

To prevent any unlawful combination among the tribunals, each has its *censor* appointed: This is an officer whose duty is merely to watch over the proceedings of the court, without deciding upon any thing himself. He assists therefore at all assemblies, revises all their acts, and without acquainting the court in the least with either his sentiments or intentions, immediately informs the emperor of what he judges to be amiss. He likewise gives information of the behaviour of the mandarins, either in the public administration of affairs, or in their private conduct; nay, sometimes he will not scruple to reprimand the emperor for what he supposes to be erroneous in his conduct.

67

Censors.

These censors are never removed from their places but in order to be promoted; and thus, holding their offices for life, they have the greater courage to speak out when they observe any impropriety or abuse. Their accusation is sufficient to set on foot an inquiry, which generally leads to a proof; in which case the accused is discharged from his office, and never held in any estimation afterwards. The complaints of the censors, however, are referred to the very tribunals against whose members they complain; though, being afraid of an accusation themselves, they very seldom pass sentence against the accusers.

Besides all this, the censors also form a tribunal of their own, named *tou-tche-yven*. Its members have a right of remonstrating with the emperor, whenever his own interest or that of the public renders it necessary. They inspect all lawyers and military men in public employments. "In short (says M. Grosier), they are, morally speaking, placed between the prince and the mandarins; between the mandarins and the people; between the people and families; between families and individuals; and they generally unite to the importance of their office incorruptible probity and invincible courage. The sovereign may, if he proceeds to rigour, take away their lives; but many of them have patiently suffered death, rather than betray the cause of truth, or wink at abuses. It is not sufficient therefore to have got rid of one, they must all be treated in the same manner; the last that might be spared would tread in the same steps with no less resolution than those who went before him. In the annals of no nation do we find an example of such a tribunal, yet it appears to be necessary in all, without exception. We must not, however, imagine, that the privileges of a censor gave him a right to forget his duty to his sovereign, or to communicate to the public those remarks which he takes the liberty of making to him: were he only to give the least hint of them to his colleagues, he would be punished with death; and he would share the same fate did he, in any of his representations, suffer a single word, inconsistent with moderation or respect, to escape him."

68

There are still two other courts in China, both of them peculiar to the empire, which deserve to be mentioned. The first is that of princes; and which, in conformity with its title, is composed of princes only.

Two courts
peculiar to
China.

In

China.

In the registers of this tribunal are inscribed the names of all the children of the imperial family as soon as they are born; and to these are also consigned the dignities and titles which the emperor confers upon them. This is the only tribunal where the princes can be tried; and here they are absolved or punished according to the pleasure of the judges.

The other tribunal is that of history, called by the Chinese *han-lin-yuan*. It is composed of the greatest geniuses of the empire, and of men of the most profound erudition. These are entrusted with the education of the heir apparent to the throne, and the compilation and arrangement of the general history of the empire; which last part of their office renders them formidable even to the emperor himself. From this body the mandarins of the first class, and the presidents of the supreme class, are generally chosen.

69
Filial piety
the basis of
all their
laws.

The basis of all the civil laws of the Chinese is filial piety. Every mandarin, who is a governor either of a province or city, must instruct the people assembled round him twice a-month, and recommend to them the observance of certain salutary rules, which are summed up in a few short sentences, and such as no person can ever be supposed capable of forgetting.

70
Of their
marriages.

The Chinese are allowed only to have one wife, whose rank and age must be nearly equal to that of their husbands; but they are allowed to have several concubines, whom they may admit into their houses without any formality, after paying the parents a sum of money, and entering into a written engagement to use their daughters well. These concubines, however, are all in subjection to the lawful wife; their children are considered as hers; they address her as mother, and can give this title to her only. A person that has once been married, whether man or woman, may lawfully marry again, but it is then no longer necessary to study equality of age or condition. A man may choose his second wife from among his concubines; and, in all cases, this new marriage requires very few formalities. A widow is absolute mistress of herself, and can neither be compelled by her parents to marry again, nor to continue in a state of widowhood, contrary to her own inclination. Those of moderate rank, however, who have no children, do not enjoy the same privilege; as the parents of the former husband can dispose of her in marriage, not only without her consent, but without her knowledge. The law authorises the disposal of them in this manner, in order to indemnify the relations of the deceased husband for the money they may have cost him. If the wife is left big with child, this cannot take place, until she is delivered; nor can it be done at all if she brings forth a son. There are likewise two exceptions; 1. when the parents of the widow assign her a proper maintenance; and, 2. if the widow embraces a religious life, and becomes a bonzesse.

71
Divorces,
unlawful
marriages,
&c.

Divorces are allowed in China in cases of adultery, mutual dislike, incompatibility of tempers, jealousy, &c. No husband, however, can put away or sell his wife until a divorce is legally obtained; and if this regulation be not strictly observed, the buyer and seller become equally culpable. If a wife, lawfully married, privately withdraws herself from her husband, he may

immediately commence an action at law; by the sentence of which she becomes his slave, and he is at liberty to sell her to whom he pleases. On the other hand, if an husband leaves his wife for three years, she is at liberty, after laying her case before the mandarins, to take another husband; but if she were to anticipate their consent, she would be liable to a severe punishment.

Marriage is deemed illegal in China in the following cases. 1. If a young woman has been betrothed to a young man, and presents have been given and received by the parents of the intended husband and wife. 2. If in the room of a beautiful young woman another be substituted of a disagreeable figure; or if the daughter of a free man marry his slave; or if any one give his slave to a free woman, pretending to her parents that he is his son or relation. In all these cases the marriage is null and void; and all those who have had any share in making up the match are severely punished.

3. Any mandarin of letters is forbidden to form an alliance with any family residing in the province or city of which he is governor.

4. No Chinese youth can enter into a state of marriage during the time of mourning for his father or mother; and if promises have been made before, they cease immediately on that event taking place. After the usual time of mourning is expired, however, the parents of the intended bride are obliged to write to those of the young man, putting him in mind of his engagement.

5. Marriage is also suspended when a family experiences any severe misfortune, and even if a near relation were thrown into prison; though this may be set aside, provided the unfortunate person give his consent.

6. Two brothers cannot marry two sisters; nor is a widower at liberty to marry his son to the daughter of a widow whom he chooses for his own wife. A man is also forbidden to marry any of his own relations, however distant the degree of consanguinity may be between them.

In China every father of a family is responsible for the conduct of his children, and even of his domestics; all those faults being imputed to him which it was his duty to have prevented. Every father has the power of selling his son, "provided (says the law) the son has a right of selling himself." This custom, however, is barely tolerated among the middling and inferior ranks; and all are forbidden to sell them to comedians, or people of infamous character, or very mean stations.

In China a son remains a minor during the whole lifetime, and is even liable for the debts contracted by his father, those from gaming only excepted. Adoption is authorised by law, and the adopted child immediately enters into all the rights of a lawful son; only the law gives a right to the father of making a few dispositions in favour of his real children. The children, however, whether adopted or not, cannot succeed to the dignity or titles of their father, though they may to his estate. The emperor alone can confer honours; and even then they must be resigned when the person attains the age of 70; though this resignation is considered as an advice rather than a law.

China.

China.

law. The will of a father cannot be set aside in China on account of any informality; nor can any mother in this empire make a will.

Though the Chinese laws authorise slavery, yet the power of the master extends only to those matters which concern his own service; and he would be punished with death for taking advantage of his power to debauch the wife of his slave.

By the laws of China husbandmen are exempt from the payment of taxes after he has begun to till the earth to the beginning of harvest.

72
Criminal
laws in
China.

In criminal matters every person accused must be examined before five or six tribunals; and whose enquiries are directed not only against him, but against his accuser, and the witnesses that appear in the cause. He is, however, obliged to remain in prison during the process: "but (says M. Grosier) the Chinese prisons are not horrible dungeons like those of so many other nations; they are spacious, and have even a degree of convenience. One of the mandarins is obliged to inspect them frequently; and this he does with the greater punctuality, as he must answer for those who are sick. He is obliged to see them properly treated, to send for physicians, and to supply them with medicines at the emperor's expence. If any of them dies, he must inform the emperor, who perhaps will order some of the higher mandarins to examine whether the former has discharged his duty faithfully or not.

73
Method of
inflicting
the basti-
nado.

The slightest punishment in China is the bastinado; and the number of blows is to be determined by the degree of the offender's guilt. Twenty is the lowest number; and in this case the punishment is considered as having nothing infamous in it, but being only a simple paternal correction. In this way the emperor sometimes orders it to be inflicted on his courtiers; which does not prevent them from being afterwards received into favour, and as much respected as before. Every mandarin may inflict the bastinado when any one forgets to salute him, or when he sits in judgment in public. The instrument of correction is called *pan-tsee*, and is a piece of bamboo a little flattened, broad at the bottom, and polished at the upper extremity, in order to manage it more easily with the hand. When the punishment is to be inflicted, the magistrate sits gravely behind a table, having on it a bag filled with small sticks, while a number of petty officers stand around him, each furnished with these *pan-tsees*, and waiting only for his signal to make use of them. The mandarin then takes out one of the little sticks contained in the bag, and throws it into the hall of audience. On this the culprit is seized and stretched out with his belly towards the ground; his breeches are pulled down to his heels, and an athletic domestic applies five smart blows with his *pan-tsee*. If the judge draws another small stick from the bag, another officer succeeds, and bestows five more blows; and so on until the judge makes no more signals. When the punishment is over, the criminal must throw himself on his knees, incline his body three times to the earth, and thank the judge for the care he takes of his education.

For faults of a higher nature, the carrying of a wooden collar, called by the Portuguese the *cangue*, is

inflicted. This machine is composed of two pieces of wood hollowed out in the middle, which, when put together, leave sufficient room for the neck. These are laid upon the shoulders of the criminal, and joined together in such a manner, that he can neither see his feet nor put his hands to his mouth; so that he is incapable of eating without the assistance of another. This disagreeable burden he is obliged to carry day and night; its weight is from 50 to 200 pounds, according to the enormity of the crime, to which the time of carrying it is also proportioned. For robbery, breaking the peace, or disturbing a family, or being a notorious gambler, it is generally carried three months. During all this time the criminal is not allowed to take shelter in his own house, but is stationed for a certain space of time, either in some public square, the gate of a city or temple, or perhaps even of the tribunal where he was condemned. On the expiration of his term of punishment, he is again brought before the judge, who exhorts him in a friendly manner to amend; and after giving him 20 sound blows discharges him.

Banishment is inflicted for crimes of a nature inferior to homicide, and the duration is often for life, if the criminals be sent into Tartary. Some culprits are condemned to drag the royal barks for three years, or to be branded in the cheeks with a hot iron, indicating the nature of their transgressions. Robbery between relations is more severely punished than any other; and that is accounted the most atrocious where younger brothers or nephews appropriate to themselves beforehand any part of the succession in which they have a right to share with their elder brothers or nephews.

Information against a father or mother, grandfather or grandmother, uncle or eldest brother, even though the accusation be just, is punished with 100 blows of the *pan-tsee*, and three years banishment. If the accusation be false, it is punished with death. Deficiency in proper filial respect to a father, mother, grandfather, or grandmother, is punished with 100 blows of the *pan-tsee*; abusive language to these relations is death by strangling; to strike them is punished by beheading; and if any one presumes to hurt or maim them, his flesh is torn from his bones with red hot pincers, and he is cut into 1000 pieces. Abusing an elder brother is punished with 100 blows of the *pan-tsee*; striking him, with the punishment of exile.

Homicide, even though accidental, is punished with death in China. A rope about six or seven feet in length, with a running noose, is thrown over the criminal's head; and a couple of domestics belonging to the tribunal pull it strongly in different directions. They then suddenly quit it, and in a few moments give a second pull; a third is seldom necessary to finish the business. Beheading is accounted in China the most dishonourable of all punishments, and is reserved only for desperate assassins, or those who commit some crime equally atrocious with murder. To be cut in a thousand pieces is a punishment inflicted only upon state criminals or rebellious subjects. It is performed by tying the criminal to a post, scalping the skin from the head, and pulling it over the eyes. The executioner then tears the flesh from different parts of the

China. unhappy wretch's body; and never quits this horrible employment till mere fatigue obliges him to give over: the remains of the body are then left to the barbarous spectators, who finish what he has begun. Though this punishment, however, has been inflicted by some emperors with all the dreadful circumstances just mentioned, the law orders only the criminal's belly to be opened, his body to be cut into several pieces, and then thrown into a ditch or river.

The torture, both ordinary and extraordinary, is used in China. The former is applied to the hands or feet: for the hands, small pieces of wood are applied diagonally between the fingers of the criminal; his fingers are then tied close with cords, and he is left for some time in that painful situation. The torture for the feet is still worse. An instrument, consisting of three cross pieces of wood, is provided, that in the middle being fixed, the others moveable. The feet of the criminal are then put into this machine, which squeezes them so close that the ankle bones become flat. The extraordinary torture consists in making small gashes in the body, and then tearing off the skin like thongs. It is never applied but for some great crime, such as treason, or where the criminal's guilt has been clearly proved, and it is necessary to make him discover his accomplices.

78
M. Grosier's general view of the Chinese laws.

Notwithstanding these dreadful punishments, M. Grosier is at great pains to prove that the laws of the Chinese, with regard to criminal matters, are extremely mild. "One law (says he) will no doubt appear exceedingly severe and rigorous; it inflicts the punishment of death on those who use pearls. Those who read the history of China will be apt to fall into certain mistakes respecting the penal laws of that nation. Some of its sovereigns have indulged themselves in gratifying sanguinary caprices which were not authorised by the laws, and which have often been confounded with them; but these princes are even yet ranked among the number of tyrants, and their names are still abhorred and detested throughout the whole empire. The Chinese, in their criminal procedure, have a great advantage over all other nations: it is almost impossible that an innocent man should ever become a victim to a false accusation: in such cases the accuser and witnesses are exposed to too much danger. The slowness of the process, and the numberless revisions it undergoes, are another safeguard for the accused. In short, no sentence of death is ever carried into execution until it has been approved and confirmed by the emperor. A fair copy of the whole process is laid before him; a number of other copies are also made out, both in the Chinese and Tartar languages, which the emperor submits to the examination of a like number of doctors, either Tartars or Chinese. When the crime is of great enormity, and clearly proved, the emperor writes with his own hand at the bottom of the sentence, "When you receive this order, let it be executed without delay." In cases where the crime, though punishable by death according to law, is ranked only in the ordinary class, the emperor writes at the bottom of the sentence, "Let the criminal be detained in prison, and executed in autumn;" that being the season in which they are generally executed, and all on the same day.

The emperor of China never signs an order for the

execution of a criminal till he has prepared himself by fasting. Like other monarchs he has the power of giving pardons; but in this respect is much more limited than any other. The only cases in which the Chinese monarch can remit the punishment inflicted by law are, 1. To the son of a widow who has not married again; 2. To the heir of an ancient family; 3. The descendants of great men or citizens who have deserved well of their country; and, 4. lastly, The sons or grandsons of a mandarin, who has become illustrious, and distinguished himself by faithfully discharging the duties of his office. Neither a child, nor a man of very advanced age, can be cited before a tribunal. The son of a very aged father and mother is pardoned, if private property or the public peace be not hurt by giving him a pardon; and if the sons of such a father and mother be all guilty, or accomplices in the same crime, the youngest is pardoned in order to comfort his parents.

In China the accused are always treated with tenderness and lenity, being accounted innocent until their guilt be clearly proved; and even then, liberty excepted, they are scarce allowed to want for any thing. A jailor is punished who behaves rigorously towards his prisoners; and the judges must likewise answer at their peril for any additions to the severity of the law; deposition being the slightest punishment inflicted upon them.

Substitution is sometimes allowed by the laws of China; so that the near relation of a guilty person may put himself in the criminal's place, provided, however, that the chastisement be slight, and the accused his ancient friend. The sons, grandsons, wife, and brothers of a banished Chinese, are allowed to follow him into exile; and the relations of all persons are permitted to visit them in prison, and to give them every assistance in their power; to do which good offices they are even encouraged, instead of being prevented.

Every city in China is divided into different quarters, each of which is subjected to the inspection of a certain officer, who is answerable for whatever passes in the places under his jurisdiction. Fathers of families, as we have already observed, are answerable for the conduct of their children and domestics. Neighbours are even obliged to answer for one another, and are bound to give every help and assistance in cases of robbery, fire, or any accident, especially in the night-time. All the cities are furnished with gates, which are barricaded on the commencement of night. Centinels are also posted at certain distances throughout the streets, who stop all who walk in the night, and a number of horsemen go round the ramparts for the same purpose; so that it is almost impossible to elude their vigilance by favour of the darkness. A strict watch is also kept during the day-time; and all those who give any suspicion by their looks, accent, or behaviour, are immediately carried before a mandarin, and sometimes even detained until the pleasure of the governor be known.

Private quarrels do not often happen in China, and it is rare that they are attended with a fatal issue. The champions sometimes decide the quarrel with their fists, but most frequently refer the case to a mandarin, who very often orders them both a sound drubbing.

China.

crimes may be pardoned.

80

Of the cities and their government.

China.

bing. None but military people are permitted to wear arms in public; and this privilege is extended even to them only during the time of war, or when they accompany a mandarin, mount guard, or attend a review. Prostitutes are not allowed to remain within the walls of a city, or to keep a house of their own even in the suburbs. They may, however, lodge in the house of another; but that other is accountable for every disturbance which may happen on their account.

81

Borrowing
of money.

In all the Chinese cities, and even in some of their ordinary towns, there is an office where money may be borrowed upon pledges at the common rate of the country; which, however, is no less than 30 per cent. Every pledge is marked with a number when left at the office, and must be produced when demanded; but it becomes the property of the office if left there a single day longer than the term agreed upon for the payment of the money. The whole transaction remains an inviolable secret; not even the name of the person who leaves the pledge being inquired after.

82

Of the Chi-
nese roads.

Great attention is paid by the administration of China to the convenience of travellers. The roads are generally very broad, all of them paved in the southern provinces, and some in the northern; but neither horses nor carriages are allowed to pass along these. In many places valleys have been filled up, and rocks and mountains cut through, for the purpose of making commodious high ways, and to preserve them as nearly as possible on a level. They are generally bordered with very lofty trees, and in some places with walls eight or ten feet high, to prevent travellers from going into the fields; but openings are left in proper places, which give a passage into cross roads that lead to different villages. Covered seats are erected on all the great roads, where travellers may shelter themselves from the inclemency of the weather; temples and pagods are also frequent, into which travellers are admitted without scruple in the day-time, but often meet with a refusal in the night. In these the mandarins only have a right to rest themselves as long as they think proper. There is, however, no want of inns on the great roads, or even the cross ones in China; but they are ill supplied with provisions; and those who frequent them are even obliged to carry beds along with them to sleep on, or else take up with a plain mat.

Towers are erected on all the roads of this great empire, with watch-boxes on the top, with flag-staffs, for the convenience of signals in case of any alarm. These towers are square, and generally constructed of brick, but seldom exceed twelve feet in height. They are built, however, in sight of one another, and are guarded by soldiers, who run with great speed from one to another, carrying letters which concern the emperor. Intelligence of any remarkable event is also conveyed by signals; and thus the court is informed with surprising quickness of any important matter. Those which are built on any of the roads conducting to court, are furnished with battlements, and have also

very large bells of cast iron. According to law these towers should be only five *lys*, about half a French league, distant from one another.

China.

There is no public post-office in China, though several private ones have been established; but the couriers and officers charged with dispatches for the empire have only a right to make use of them. This inconvenience, however, excepted, travellers find conveyance very easy from one part of China to another. Great numbers of porters are employed in every city, all of whom are associated under the conduct of a chief, who regulates all their engagements, fixes the price of their labour, receives their hire, and is responsible for every thing they carry. When porters are wanted, he furnishes as many as may be necessary, and gives the same number of tickets to the traveller; who returns one to each porter when they have conveyed their loads to an appointed place. These tickets are carried back to the chief, who immediately pays them from the money he received in advance. On all the great roads in China there are several offices of this kind, which have a settled correspondence with others; the travellers therefore have only to carry to one of these offices a list of such things as they wish to have transported: this is immediately written down in a book; and though there should be occasion for two, three, or four hundred porters, they are instantly furnished. Every thing is weighed before the eyes of their chief, and the hire is five pence per hundred weight for one day's carriage. An exact register of every thing is kept in the office; the traveller pays the money in advance, after which he has no occasion to give himself any farther trouble: on his arrival at the city he designs, his baggage is found at the corresponding office, and every thing is delivered to him with the most scrupulous exactness.

83

Method of
convey-
ance.

The custom-houses are here regulated by the general police of the country; and according to M. Grofier's account, these custom-house officers are the most civil in the world. They have no concern with any class of people but the merchants, whom they take care not to distress by any rigorous exactions; neither, though they have authority to do so, do they stop travellers till their baggage is examined, nor do they ever require the smallest fee from them. Duties are paid either by the piece or the load; and in the former case credit is given to the merchant's book without asking any questions. A mandarin is appointed by the viceroy of each province to inspect the custom-houses of the whole district; and the mandarins have also the care of the post offices.

84

Custom-
houses.

In former times the only money used in China was made of small shells, but now both silver and copper coin are met with. The latter consists of round pieces about nine-tenths of an inch (A) in diameter, with a small square hole in the middle, inscribed with two Chinese words on one side, and two Tartar ones on the other. The silver pieces are valued only by their weight. For the convenience of commerce the metal is therefore cast into plates of different sizes; and for want of small coin, a Chinese always carries about

85

Money of
the empire.

(A) The Chinese foot is longer by one hundredth part than the French, and the inch is divided into ten parts.

China.

about him his scales, weights, and a pair of scissars to cut the metal. This operation is performed by putting the silver between the scissars, and then knocking them against a stone till the pieces drop off. In giving of change, however, people have no right to value silver by the numerical value of copper, this being entirely regulated by the intrinsic value of the metals. Thus, an ounce of silver will sometimes be worth 1000 copper pieces, and sometimes only 800; and thus the copper money of China may frequently be sold for more than it would pass for in commerce. The emperor would lose much by this recoinage, were he not the sole proprietor of all the copper mines in China. It is, however, expressly forbidden to employ copper coin in any manufacture where it might be employed as plain copper, and it is also forbidden to be sold for the purpose of melting: but, if the price of the metal has not fallen, the infraction of this law is not very severely punished. On the other hand, if the value of unwrought copper exceeds that of the coin, a quantity of the latter is issued out to restore the equilibrium.

To keep up a constant circulation of all the coin in the empire, the Chinese government are attentive to preserve an equilibrium between the proportional value of the gold and silver; that is, to regulate the intrinsic value of each in such a manner that the possessor of silver may not be afraid to exchange it for copper, nor the possessor of copper for silver. The method used for this purpose is, when silver becomes scarce, to make all the payments for some time in silver; but if copper, to make them all for some time in that metal only.

86
Of the Chinese commerce.

The commerce of China is under the inspection of the tribunal of finances; but on this subject the Chinese entertain an opinion quite different from that of the Europeans. Commerce, according to them, is only useful as far as it eases the people of their superfluities, and procures them necessaries. For this reason they consider even that which is carried on at Canton as prejudicial to the interest of the empire. "They take from us (say the Chinese) our silks, teas, and porcelain: the price of these articles is raised through all the provinces: such a trade therefore cannot be beneficial. The money brought us by Europeans, and the high-priced baubles that accompany it, are mere superfluities to such a state as ours. We have no occasion for more bullion than what may be necessary to answer the exigencies of government, and to supply the relative wants of individuals. It was said by Kouan-tse, two thousand years ago, That the money introduced does not enrich a kingdom in any other way, than as it is introduced by commerce. No commerce can be advantageous long, but that which consists in a mutual exchange of things necessary or useful. That trade, whether carried on by barter or money, which has for its object the importing of articles that tend to the gratification of pride, luxury, or curiosity, always supposes the existence of luxury: but luxury, which is an abundance of superfluities among certain classes of people, supposes the want of necessaries among a great many others. The more horses the rich put to their carriages, the greater will be the number of those who are obliged to walk on foot; the larger and more magnificent their houses

are, so much the more confined and wretched must those of the poor be; and the more their tables are covered with a variety of dishes, the more must the number of those increase who are reduced to the necessity of feeding upon plain rice. Men, united by society in a large and populous kingdom, can employ their industry, talents, and economy, to no better purpose than to provide necessaries for all, and procure convenience for some."

The only commerce considered by the Chinese as advantageous to their empire, is that with Russia and Tartary; by which they are supplied with those furs so necessary in the northern provinces. The disputes concerning the limits of the respective empires of Russia and China seem to have paved the way to this commerce. These disputes were settled by treaty on the 27th of August 1689, under the reign of Ivan and Peter Alexiowitz. The chief of the embassy on the part of Russia was Golovin governor of Siberia; and two Jesuits were deputed on the part of the emperor of China; and the conferences were held in Latin, with a German in the Russian ambassador's train, who was acquainted with that language. By this treaty the Russians obtained a regular and permanent trade with China, which they had long desired; but in return they yielded up a large territory, besides the navigation of the river Amour. The first intercourse had taken place in the beginning of the 17th century; at which time a small quantity of Chinese merchandize was procured by some Russian merchants from the Kalmuck Tartars. The rapid and profitable sale of these commodities encouraged certain Siberian Wayvodes to attempt a direct and open communication with China. For this purpose several deputations were sent to the emperor; and though they failed of obtaining the grant of a regular commerce, their attempts were attended with some consequences of importance. Thus the Russian merchants were tempted to send traders occasionally to Peking; by which means a faint connection was preserved with that metropolis. This commerce, however, was at last interrupted by the commencement of hostilities on the river Amour; but after the conclusion of the treaty in 1689, was resumed with uncommon alacrity on the part of the Russians: and the advantages thence arising were found to be so considerable, that a design of enlarging it was formed by Peter the Great. Isbrand Ides, a native of the duchy of Holstein, then in the Russian service, was therefore dispatched to Peking in 1692; by whose means the liberty of trade, before confined to individuals, was now extended to caravans. In the mean time, private merchants continued to trade as before, not only with the Chinese, but also at the head quarters of the Mogul Tartars. The camp of these roving Tartars, which was generally stationed near the confluence of the Orhon and Toulra rivers between the southern frontiers of Siberia and the Mogul desert, thus became the seat of an annual fair. Complaints, however, were soon made of the disorderly behaviour of the Russians; on which the Chinese monarch threatened to expel them from his dominions entirely, and to allow them neither to trade with the Chinese nor Moguls. This produced another embassy to Peking in 1719, when matters were again adjusted to the

China.

87
History of the trade with Russia.

China.

the satisfaction of both parties. The reconciliation, was of no long duration; for the Russians having soon renewed their disorderly behaviour, an order for their expulsion was issued in 1722, and all intercourse between the two nations forbidden. The differences were once more made up in 1727, and a caravan allowed to go to Peking once in three years, provided it consisted of no more than 100 persons; and that during their stay their expences should not, as formerly, be defrayed by the emperor of China. The Russians at the same time obtained permission to build a church within the precincts of the caravanfary; and that four priests were allowed to reside at Peking for the celebration of divine service; the same indulgence being granted to some Russian scholars, for the purpose of learning the Chinese language, and qualifying themselves for being interpreters between the two nations. This intercourse continued till the year 1755; since which time no more caravans have been sent to China. It was first interrupted by a misunderstanding betwixt the two courts; and though that difference was afterwards made up, no caravans have been sent ever since. The empress of Russia, sensible that the monopoly of the fur trade (which was entirely confined to the caravans belonging to the crown, and prohibited to individuals) was prejudicial to commerce, gave it up in favour of her subjects in 1762; and the centre of commerce betwixt the two nations is now at Kiatka. Here the trade is entirely carried on by barter. The Russians are prohibited from exporting their own coin; finding it more advantageous to take goods in exchange than to receive bullion at the Chinese standard. The principal exports from Russia are furs of different kinds; the most valuable of which are those of sea-otters, beavers, wolves, foxes, martins, sables, and ermines; the greater part of which are brought from Siberia and the newly discovered islands; but as they cannot supply the demand, there is a necessity for importing foreign furs to Petersburg, which are afterwards sent to Kiatka. Various kinds of cloth are likewise sent to China, as well as hardware, and live cattle, such as horses, camels, &c. The exports from China are, raw and manufactured silk, cotton, porcelain, rhubarb, musk, &c. The government of Russia likewise reserves to itself the exclusive privilege of purchasing rhubarb. It is brought to Kiatka by some Bukharian merchants, who have entered into a contract to supply the crown with it in exchange for furs: the exportation of the best rhubarb is forbidden under severe penalties, but yet is procured in sufficient quantities, sometimes by clandestinely mixing it with inferior roots, and sometimes by smuggling it directly. Great part of Europe is supplied with rhubarb from Russia.

88
Emperor's
revenue.

The revenue of the emperor of China amounts to more than 41 millions sterling; and might easily be increased, did the sovereign incline to burden his subjects with new impositions. The annual expences of government are indeed immense, but they are regulated in such a manner as never to be augmented but in cases of the utmost necessity; it even happens very often that administration makes greater savings every year. When this happens to be the case, the surplus serves to increase the general treasure of the empire, and prevents the necessity of new impositions in time

N^o 77.

of war, or other public calamities. The greater part of the taxes are paid in kind; those, for instance, who breed silk worms, pay their taxes in silk, the husbandmen in grain, the gardeners in fruits, &c. This method, at the same time that it is exceedingly convenient for the subject, is no way detrimental to the public interest. There are numbers of people every where in the service of government, who are thus furnished with food and clothing; so that the commodities collected as taxes are almost consumed in the provinces where they are levied; what remains is sold for the behoof of the emperor, and the money deposited in the imperial treasury. The taxes paid in money arise principally from the customs and sale of salt (which belongs entirely to the emperor), from the duties paid by vessels entering any port, and from other imposts on various branches of manufactures. Excepting these, the trader scarcely contributes any thing to the exigencies of the state, and the mechanic nothing at all; the whole burden of taxation thus falling upon the husbandman. This burden is regulated in proportion to the extent and fertility of his lands; and the greatest care has been taken to manage matters so, that he may neither be overcharged in the imposition nor harassed in the levying of the duties. "The registering of lands (says M. Grosier), so often and to no purpose projected in France, has been long practised in this empire, notwithstanding its prodigious extent."

The levying of taxes in China is as simple as the nature of the thing will admit of. The duties levied from towns and villages are carried to cities of the third class; then they are conducted to those of the second; then to those of the first; and at last to the capital. The levying and imposition of taxes is submitted to the tribunal of finances; and matters are so managed, that besides the consumption in each district for discharging the ordinary expences of government, something is left by way of reserve for answering accidental demands, and to be ready in cases of necessity. This sum becomes gradually less from the capital to cities of the first, second, and third class. A proper statement of what is paid in the provinces, of what is reserved in the different cities, or contained in the different treasuries of the empire, is subjected to the examination of the grand tribunal of finances. This revises the whole, and keeps an exact account of what is consumed, and of whatever surplus may be left.

Lending money upon interest has been in use in China for about 2000 years. It has often been abolished, and as often established. The interest, as has been already hinted, is no less than 30 per cent. and the year is only lunar. A tenth part of this interest is paid monthly; and concerning neglects of payment, the following laws have been enacted. "However much the debt may have accumulated by months or years, the principal and interest shall remain always the same. Whoever infringes this law shall receive 40 blows of a *pan-tsee*; or an hundred, if he uses any artifice to add the principal and interest together." This law is explained by the following. "Whoever shall be convicted before a mandarin of not having paid a month's interest, shall receive ten blows; twenty for two months, and thirty for three; and in this manner as far as sixty; that is to say, to the sixth month. The debtor,

money, and
deficiencies
in paying
interest.

China. debtor is then obliged to pay principal and interest; but those who obtain payment by using violence and force, are condemned to receive 24 blows.

Many Chinese writers have endeavoured unsuccessfully to show why government should allow such exorbitant interest to be taken for money; but the most satisfactory and rational account seems to be, that the great interest of money prevents the rich from purchasing much land; as landed estates would only embarrass and impoverish them, their produce being so much inferior to that of money. The patrimony of a family in China is seldom divided; and it never happens there, as in almost every other country, that wealth and riches are engrossed by one part of the nation, while the other possesses nothing.

91 Agriculture is by the Chinese considered as the first and most honourable of all professions; so that in this empire the husbandman enjoys many and great privileges, while the merchant and mechanic are much less esteemed. Part of the crop is allowed to be used in distillation; but if the harvest happens to be bad, this operation is prohibited. In China, the tillage of the earth is not only encouraged by law, but also by the example of the emperor, who annually tills the earth with his own hands. The beginning of spring in China is always reckoned to be in the month of February; but it belongs to the tribunal of mathematics to determine the precise day. The tribunal of ceremonies announces it to the emperor by a memorial; in which every thing requisite to be done by him is mentioned with the most scrupulous exactness. The sovereign then names 12 of the most illustrious persons in his court to accompany him, and to hold the plough after he has performed his part of the ceremony. Among these there are always three princes of the blood, and nine presidents of supreme courts; and if any of them are too old and infirm to undergo the fatigue, the substitutes must be authorised by the emperor. The festival is preceded by a sacrifice, which the emperor offers up to *Chang-ti* (the supreme God); after which he and his attendants prepare themselves by three days fasting and continence. Others are appointed by the emperor, on the evening before the ceremony, to go and prostrate themselves at the sepulchre of his ancestors, and to acquaint them, that, on the day following, he intends to celebrate a grand sacrifice. This is offered up on a small mount a few furlongs distant from the city, which, by the indispensable rules of the ceremony, must be 50 feet in height. The *Chang-ti* is invoked by the emperor, who sacrifices under the title of sovereign pontiff, and prays for an abundant harvest in favour of his people. He then descends, accompanied by the three princes and nine presidents who are to put their hands to the plough along with him; the field set apart for this purpose being at a small distance from the mount. Forty labourers are selected to yoke the oxen, and to prepare the seeds which the emperor is to sow; and which are of five different kinds, viz. wheat, rice, two kinds of millet, and beans. They are brought to the spot in magnificent boxes, carried by persons of the most distinguished rank. The emperor then lays hold of the plough, and turns up several furrows; the princes of the blood do the same, and then the presidents; after which the emperor throws into the furrows the

91 Agriculture greatly encouraged.

92 Ceremony of the emperor tilling the earth with his own hands.

five kinds of seeds already mentioned: lastly, four pieces of cotton-cloth, proper for making dresses, are distributed to each of the labourers, who assist in yoking the oxen and preparing the seeds; and the same presents are made to 40 other persons who have only been spectators of the ceremony.

“We must not (says M. Grosier) judge of the Chinese peasants from those of Europe, especially in what relates to the lights acquired by education. Free schools are very numerous in every province of China, and even some of the villages are not destitute of this advantage. The sons of the poor are there received as readily as those of the rich; their duties and their studies are the same; the attention of the masters is equally divided between them; and from this obscure source talents often spring, which afterwards make a conspicuous figure on the grand stage of life. Nothing is more common in China than to see the son of a peasant governor of that province in which his father had long toiled in cultivating only a few acres. The father himself, if taken from his plough, and elevated to a superior sphere, might, by reviving the instruction he received in his youth, and especially if he be endowed with genius, find himself fully competent for his new employment.”

94 The Chinese have been greatly reproached with the inhuman practice of murdering their children; but though our author cannot deny that they are guilty of this practice, he excuses them by saying, that “the crime when committed in China is commonly owing to the fanaticism of idolatry; a fanaticism which prevails only among the lowest of the people. It is either in obedience to the oracle of a bonze, to deliver themselves from the power of magic spells, or to discharge a vow, that these infatuated wretches precipitate their children into the river: they imagine that, by doing so, they make an expiatory sacrifice to the spirit of the river. All nations of antiquity almost have disgraced themselves by the like horrid practices; but the Chinese are far from countenancing this barbarity on that account. Besides, these criminal sacrifices are never practised but in certain cantons of China, where the people, blinded by idolatry, are the dupes of prejudice, fanaticism, and superstition.—It often happens also, that the bodies of those children which are seen floating on the water have not been thrown into it till after their death; and this is likewise the case with those which are found in the streets, or lying near the public roads. The poverty of the parents suggests this dismal resource, because their children are then buried at the expence of the public. Exposing of children in public places is a custom tolerated in China; and government employs as much vigilance to have them carried away in the morning, as it bestows care on their education. This is certainly giving people intimation to expose their children in the night-time, and no doubt encourages the practice; but the dictates of humanity are here united to those of sound policy. No law in China authorises mutilation: there are indeed eunuchs in the empire, but their number is much less than what it is generally supposed to be by Europeans. The greater part of the eunuchs belonging to the emperor and empresses have no higher employment than that of sweeping the courts of justice.”

95
Gazette of
Peking.

Like the capital cities of European kingdoms, Peking, the metropolis of the Chinese empire, is furnished with a gazette, which circulates into the remotest provinces, and which is even considered by administration as an essential part of the political constitution. It is printed daily at Peking, and contains an account of all those objects to which the attention of administration is directed. In this gazette may be seen the names of all those mandarins who are stripped of their employments, and the causes of their disgrace; it mentions also the names of all those delinquents who are punished with death; of the officers appointed to fill the places of the disgraced mandarins; the calamities which have afflicted any of the provinces; the relief given by government; and the expences incurred by administration for the subsistence of the troops, supplying the wants of the people, repairing or erecting public works; and, lastly, the remonstrances made to the sovereign by the superior tribunals, either with regard to his public decisions or private conduct, and sometimes even with regard to both. Nothing, however, is contained in this gazette that has not immediately come from the emperor, or been submitted to his inspection; and immediate death would be the consequence of inserting a falsehood in this ministerial paper.

96
Seals of the
emperor,
mandarins,
&c.

No law or sentence, as has already been said, is of any force, until the emperor's seal has been affixed to it. This is about 8 inches square, and is made of fine jasper, a kind of precious stone much esteemed in China; of which only the emperor is allowed to have a seal. Those given to princes as marks of honour are composed of gold; the seals of the viceroys and great mandarins, of silver; while those of inferior mandarins and magistrates are made only of lead or copper. The size of those seals is greater or smaller according to the rank their possessors hold in the tribunals or as mandarins; and when any of them happens to be worn out, intimation must be sent to the next superior tribunal; on which a new one is sent, and the old one must then be delivered up. The commission of every inspector sent into the provinces must also be confirmed by the emperor's seal. The duty of these officers is to examine into the conduct of governors, magistrates, and private individuals; and instances are recorded of emperors themselves assuming the office of inspectors in some of the provinces. These officers are not only superior to all the magistrates, but even to the viceroys of the provinces themselves. When a superior magistrate behaves ill to an inferior one, the former instantly becomes the prisoner of the inspector, and is suspended from his office until he has cleared himself from every imputation laid to his charge. The viceroy, however, is allowed to enjoy his office until the report of the inspector has been transmitted to the emperor.

97
Power of
the viceroys
of provin-
ces.

These viceroys are distinguished by the title of *Tsong-tou*, and are always mandarins of the first class, possessing an almost unlimited power within their districts. They march abroad with all the pomp of royal magnificence, never quitting their palaces, on the most trifling occasion, without a guard of 100 men. A viceroy is the receiver-general of all the taxes collected in the province, transmitting them to the capital, after having reserved what he judges necessary for the

demands of his district. All law-suits must be brought before his tribunal; and he has the power of passing sentence of death, but it cannot be put in execution without being first carried to the emperor. Every three years he sends to court a report of the conduct of the mandarins subordinate to him; and according to the contents they are either continued or disgraced. Those of whom he makes an unfavourable report are punished in proportion to their delinquency; while, on the other hand, those who have the good fortune to be well reported, are rewarded in a similar proportion.

The principal mandarins are sometimes broke and dismissed from all their employments, while others are only removed some degrees lower. Those who have been degraded ten steps, run a great risk of never being employed again. These degraded mandarins are kept in perpetual remembrance of their misfortune, by being obliged to mention it in every public order they issue forth in their inferior station; thus, "I, such a mandarin, degraded one, two, three, &c. steps, command and order," &c. Over these inferior mandarins the inspector of the province has a very unlimited authority, and can, by his own power, deprive them of their employments for a great offence; nor does he consult the court, excepting where the immediate punishment of the criminal is not necessary. Every one of the mandarins, of whatever rank or denomination, is obliged, once in three years, to give in writing an exact account of the faults he has committed in the execution of his office. If he is a mandarin belonging to any of the four first classes, this confession is examined at court; but if it is made by any of the inferior ones, it must be laid before the provincial tribunal of the governor. Government, however, is not satisfied even with this confession; inquiry is made into the truth of it, and the conduct of the mandarin is scrutinized with the utmost severity, the informations being subjected to the tribunal of mandarins; where they are carefully examined, the merits and demerits of those subjected to this political inquisition carefully balanced, and their names afterwards divided into three classes. The first consists of those for whom rewards and preferment are intended; the second, for whom gentle reproof and admonition are thought necessary; and the third, of those who are to be suspended for some time, or removed altogether, from their offices. Of these last some are allowed to continue; but they receive no salary, and are not only deprived of all their emoluments, but even of their honours. If they have been guilty of any action tending to oppress the people, or to occasion a famine or scarcity among the lower ranks, their punishment is not confined to dismissal from their offices, but they are also criminally impeached. The family burying-place of every Chinese is accounted sacred; none dares cut down the trees with which it is overshadowed until they become decayed with age; and even then, not until their condition has been attested by a mandarin: but for certain crimes against government or the people, the burying-place of a mandarin is rased to the foundation. No kind of punishment, however, inflicted on a father, is supposed in the least to affect the character of his son; and therefore, when the latter is asked by the emperor concerning his family, he will perhaps coolly

China.

98
Degrada-
tion of
mandarins.

China. coolly answer, "My father was disgraced for such a crime, my grandfather was beheaded for such another," without the acknowledgment being in the least detrimental. On the contrary, by great and important services, it is possible for him to wipe out these stains from the memory of his ancestors.

Though the empire of China is governed by Tartar princes, the latter seem to bestow much more care and attention on the Chinese than their own natural subjects. Should any dispute arise between a Chinese and Tartar, the former must have greatly deviated from the rules of justice, if he is not acquitted even by those tribunals which are composed of half Chinese and half Tartars. The slightest fault committed by a Tartar mandarin is always severely punished; but the punishment of the greatest is often mitigated if the delinquent be a Chinese; and the same severity is exercised towards those of the military department. Those faults, however, are punished with the greatest severity which hurt the interests of the people; for which reason they seldom fall a sacrifice to that class of petty tyrants who in other countries prey upon and devour them. Every superior mandarin is obliged to inform himself of the faults of his inferiors, and expose them; nay, he would be punished for them himself if he did not.

99
Privileges
of princes,
&c. in Chi-
na.

Very little regard, as we have already had occasion to observe, is paid to hereditary right in China. Even the princes of the blood enjoy no other privilege by birth but that of wearing a yellow girdle; and the names of their children, with the exact time of their birth, are inscribed in a yellow book appropriated to that purpose. Collateral princes are distinguished by an orange girdle, and their children are marked in a book of a red colour. The surnames of the princes of the reigning family are determined by the emperor alone; the rest not being allowed to assume any name that too much resembles those of the Moguls or Chinese. The rank even of the emperor's sons diminishes one degree every generation; so that, at the seventh, only the eldest branch has a title to wear the yellow girdle, the rest being sunk into the rank of plain citizens. An hereditary sovereignty, however, passes from one eldest son to another; and this title cannot be forfeited, unless the possessor be guilty of some crime. In this case the emperor appoints to the succession either one of his younger brothers or a cousin; but these must be always chosen from the same branch, as the lawful branch cannot be deprived of its right without the condemnation of all who compose it. The only hereditary authority of the other princes exists among those troops called the *Tartar bands*. There they enjoy, without opposition, that rank which they derive from their birth, but in every thing else are on a level with others. They are subjected to a military examination at stated periods, and are always promoted or degraded according to the degree of skill they exhibit. The same trial is undergone by the heir apparent and his sons; the only indulgence shown them being, that schools are appointed for their particular use. The princes are likewise indulged with a tribunal appropriated on purpose for them, and before which alone they can be tried. An insult offered to a prince decorated with the yellow girdle is punished with death; but if he

China. has omitted to put it on, the aggressor escapes with a bastinading. A prince may be put to death by the emperor's consent; but he escapes every slighter corporal punishment by paying a fine. Untitled princes have very few privileges superior to those of common citizens; and are generally very poor, unless possessed of some lucrative office. Thus they are sometimes reduced to the necessity of accepting the highest pay of a common soldier in the Tartar bands. When they, or any of their children, however, enter into the marriage state, the emperor usually makes them a present of 100 ounces of silver. He will also relieve them on other occasions, assist their widows and orphans, &c. but in all this never departs from the most exact rules of economy; so that the mandarins in this respect are much better than the relations of the sovereign himself.

With regard to the ancient religion of China, F. A-¹⁰⁰ F. Amiot's account of the ancient religion of China. miot informs us, that, after making every possible research, comparing and reasoning upon his observations, he at last concluded, that "the Chinese are a distinct people, who have still preserved the characteristic marks of their first origin; a people whose primitive doctrine will be found, by those who take the trouble of investigating it thoroughly, to agree in its essential parts with the doctrine of the chosen people, before Moses, by the command of God himself, had consigned the explanation of it to the sacred records; a people, in a word, whose traditional knowledge, when freed from whatever the ignorance or superstition of later ages has added to it, may be traced back from age to age, and from epocha to epocha, without interruption, for the space of 4000 years, even to the renewal of the human race by the grandson of Noah." The *king*, or canonical books of the Chinese, every where inculcate the belief of a Supreme Being, the author and preserver of all things. Under him they mention the names of *Tien*, or Heaven; *Chang-tien*, or Supreme Heaven; *Chang-ti*, or Supreme Lord; and of *Hoang-chan-ti*, Sovereign and Supreme Lord: "Names (says M. Grosier) corresponding to those which we use when we speak of God, the Lord, the Almighty, the Most High."

According to the Chinese books, the Supreme Being is the principle of every thing that exists, and the father of all living; he is eternal, immovable, and independent; his power knows no bounds; his sight equally comprehends the past, present, and the future, penetrating even into the inmost recesses of the heart. Heaven and earth are under his government; all events, all revolutions, are the consequences of his will; he is pure, holy, and impartial; wickedness offends his sight; but he beholds with an eye of complacency the virtuous actions of men. Severe, yet just, he punishes vice in a striking manner even on the throne, and often precipitates from thence the guilty, to place upon it the man who walks after his own heart, whom he hath raised from obscurity. Good, merciful, and full of pity, he relents on the repentance of the wicked: public calamities, and the irregularities of the seasons, are only salutary warnings, which his fatherly goodness gives to men to induce them to reform and amend.

The performance of religious worship at the proper and appointed times, has given occasion to the great

China.

exactness with respect to the kalendar, which is remarkable throughout the empire of China; and all the celebrated emperors have begun their reigns with a reformation of it. Our historians, however, not contented with discovering in the Chinese religion the fundamental principles of the ancient patriarchal religion, have also found in it evident symptoms of a knowledge of the Trinity as believed among Christians. "Among the ancient Chinese characters (says M. Grosier), which have escaped the ravages of time, we find the following Δ . According to the dictionary of *Kang-hi*, this signifies union; according to the *Choue-ouen* (that book so highly esteemed in China) Δ is three united in one; it derives it from the characters *jou* (to enter or penetrate), and *ye*, one; whence it concludes, that Δ means three united, penetrated, or incorporated into one. According to another book, accounted a learned and accurate explanation of the ancient characters, ' Δ signifies strict union, harmony, the chief good of man, of heaven, and of earth; it is the union of the three *tsai* (powers, principles, or intelligences); for, united, they direct, create, and nourish together. The image $\frac{1}{1}$ (three united in one figure) is not so obscure in itself; however it is difficult to reason upon it without being deceived: on this subject it is difficult to speak.'

"Father Amiot, spite of all the objections which the critics of Europe may make, seems to conjecture, that the character Δ might have been, among the ancient Chinese, the symbol of the most holy Trinity; 'and the more so (he adds), as the ancient books furnish a number of texts, which give us reason to suppose them to have been possessed of some knowledge of this sublime mystery.' The book *See-ki* says, 'The emperor formerly offered up a solemn sacrifice every three years to the Spirit Trinity and Unity, *Chin-fan-ye*.' The following celebrated text of *Lao-tse* has long been known in Europe. '*Tao* is one by nature: the first begot the second; two produced the third; the three created all things.'

"F. Amiot quotes another passage, which appears to be no less singular. 'He who is, as it were, visible, and cannot be seen, is named *Khi*; he who may be heard, yet speaketh not to the ears, is called *Hi*; he whom, in a manner, we feel, yet cannot touch, is named *Ouei*. In vain do we interrogate our senses respecting these three: our reason, which alone can give us any satisfaction, will tell us that they make only one. Above there is no light; below there is no darkness. He is eternal; there is no name which can be given him. He resembles nothing that exists; he is an image without figure; a figure without matter: his light is surrounded by darkness. If we look up to him above, we behold no beginning; if we follow him, we discover no end. From what the *Tao* hath been at all times, conclude what he is, viz. that he is eternal: he is the beginning of wisdom.' The commentaries which explain this passage speak in such strong and precise terms, that F. Amiot forbears to quote them, lest he might incur the censure of too many incredulous readers."

101
Sacrifices.

The sacrifices of the Chinese were first offered up in the open fields, or on some mountain, upon what they call the *Tan*, which signifies a quantity of stones

thrown together in a round form, or simply a round heap of earth. A double fence, called *Kiao*, composed of turf and branches of trees, was raised around this; and, in the space left between the two fences, two lesser altars were erected on the right and left; upon which, immediately after the sacrifice offered up to the *Tien*, they sacrificed also to the *Cheng*, or good spirits of every rank, and to their virtuous ancestors. The sovereign alone had a right of sacrificing upon this *Tan*; and the custom of sacrificing to inferior spirits, according to the Chinese commentators, may be traced even to the days of *Fo-hi* himself. The same writers add, that, in addressing themselves to the *Chang-ti*, they considered him as the sovereign lord of the universe, clothed with all that power which was necessary to satisfy them with regard to the different objects of their requests; but that, in offering up their prayers to the inferior objects of worship, they only implored their protection and mediation with the *Chang-ti*.

While the empire was confined within narrow bounds, one mountain was sufficient for the sacrifices; but in process of time it became necessary to consecrate four others. These were situated at the extremities of the empire, and were supposed to correspond with the four quarters of the world; and the prince went successively every year to one of these mountains to offer up sacrifices; taking occasion at the same time to show himself to his people, and to inform himself of their wants. This custom subsisted for a long time; but at length it was found convenient to add a fifth mountain in the centre of the empire; and ever since these have been called the five *Yo*, or the five mountains of sacrifice. This method of subjecting the emperor to regular annual journeys could not but be attended with many inconveniences. It was found necessary on this account to consecrate some spot in the neighbourhood of his palace, which might be substituted for the *Yo* upon all occasions when the emperor could not repair to them. An edifice was therefore erected, which at once represented the *Kiao*, *Tan*, and the *Hall of Ancestors*. This last was a necessary part of the edifice; because it was incumbent on those who offered up sacrifices, first to repair to this hall, and acquaint their ancestors with what they were about to perform; and thither also they returned after sacrificing, to thank the same ancestors for the protection they had received from the *Chang-ti*; after which they offered up a sacrifice of thanksgiving in honour of them, and performed certain other ceremonies to show their respect. The building contained five separate halls, appropriated to different purposes: originally it had neither paintings nor ornaments of any kind, and a stair-case of nine steps conducted to the principal entrance. Afterwards, however, it was much more richly ornamented, each of the five halls being decorated with columns, over which others were placed that supported a second roof. In succeeding times it was stripped of all its ornaments, with a view to bring back religion to its primitive simplicity. Its four gates were covered with fine moss, representing the branches of which the double fence of the ancient *Kiao* were formed. The ridge of the roof was covered with the same, and the whole was encompassed by a canal filled with water at the time of offering up the sacrifices. To this a second building was added, which they called the

China.

China. the temple of neatness, and which was used only for purifications and ceremonies, the former being entirely consecrated to the worship of the Chang-ti.

At present there are only two temples in Peking, named the *Tien-tan* and the *Ti-tan*; in the construction of which all the elegance of Chinese architecture is displayed. These are both dedicated to the Chang-ti, but under different titles; in the one he is adored as the *eternal spirit*; in the other, as the creator and preserver of the world. The ceremonies of the modern sacrifices are greatly multiplied; and nothing can exceed the splendor and magnificence with which these solemnities are performed. Some time before the day appointed for the grand ceremony, the monarch, the grandees of the court, and all those whom their employments qualify to assist at the solemnity, prepare themselves by retirement, fasting, and continence; no audience is given by the emperor, and the tribunals are entirely shut; marriages, funerals, rejoicings, and entertainments of every kind, are then forbidden. At last, on the day appointed, the emperor appears attended by an innumerable multitude, and his person surrounded by a vast number of princes, lords, and officers, while every part of the temple seems to correspond with the magnificence of the sovereign; all the vases and utensils employed in the sacrifices are of gold, and cannot be applied to any other purpose; even the instruments of music are of enormous magnitude, and never used any where else. All this grandeur, however, serves only to display in a more eminent manner the humility and abasement of the monarch during his devotion; at which time he rolls in the dust, and speaks of himself before the *Chang-ti* in terms of the most abject submission and humiliation.

102
Sect of
Tao-ffe.

The purity of the ancient Chinese religion has, however, been long contaminated by many idolatrous and fanatical sects. Among these, one named *Tao-ffe* was founded by a philosopher called *Lao-kium* or *Lao-tse*, who was born 603 B. C. He died in an advanced age, leaving to his disciples a book intitled *Tao-te*, being a collection of 5000 sentences. His morality has a great resemblance to that of Epicurus. It consists principally in banishing all vehement desires and passions capable of disturbing the peace and tranquillity of the soul. According to him, the care of every wise man ought to be only to endeavour to live free from grief and pain, and to glide gently down the stream of life devoid of anxiety and care. To arrive at this happy state, he advises his followers to banish all thoughts of the past, and to abstain from every vain and useless inquiry concerning futurity, as well as all tormenting thoughts of ambition, avarice, &c. It was found by the disciples of this philosopher, however, that all their endeavours to obtain a perfect tranquillity of mind were vain, as long as the thoughts of death intervened; they therefore declared it possible to discover a composition from which drink might be made that would render mankind immortal. Hence they were led to the study of chemistry; and, like the western alchemists, wearied themselves in search of the philosopher's stone, until at last they gave themselves up to all the extravagancies of magic.

The desire of avoiding death, together with the credulity natural to unenlightened minds, quickly produced a number of converts to the sect of *Tao-ffe*.

China. Magical practices, the invocation of spirits, and the art of foretelling events by divination, quickly diffused themselves over the empire, and the imbecillity of the emperors contributed to propagate the deception. Temples consecrated to spirits quickly reared their heads in every corner of the empire; and two of the most celebrated of the sect were authorised to maintain public worship there after the form which had been prescribed by their master. At the same time they distributed, and sold at a dear rate, images of the imaginary spirits with which they had peopled the heavens and the earth. These were, by their command, worshipped as so many deities independent of the Supreme Being; and, in like manner, several of the ancient emperors were invoked as gods.

Being patronised by the emperors of several dynasties, this sect became more and more powerful. At last they had the impudence to affix, during the night-time, to one of the gates of the imperial city, a book filled with mystic characters and magical figures. At break of day they informed the emperor of the sudden appearance of this book, and publicly declared that it was fallen from heaven. This trick easily imposed upon the weak prince. He immediately repaired, with a numerous train, to the spot where the sacred volume appeared; and having taken it into his hands in a respectful manner, carried it in triumph to his palace, where he shut it up in a golden box. Another emperor carried his reverence for the sect to such an height of impiety and extravagance, as to order a celebrated *Tao-ffe* to be publicly worshipped under the name of *Chang-ti*. The sect thus patronised by the princes, and accommodated to the credulity of the vulgar, continued to gain ground in spite of every opposition from the wiser part of the people, and is still very powerful in China. At present they offer up three different victims, a hog, a fowl, and a fish, to a spirit whom they invoke. Various ceremonies, such as howling, drawing fantastical figures upon paper, making an hideous noise with kettles and drums, are used in their incantations; and though it may readily be believed that they are for the most part unsuccessful, yet their credit is still kept up by those cases in which they succeed by accident.

The chief of the *Tao-ffe* is invested by government with the dignity of grand-mandarin, which is enjoyed by his successors: he resides in a sumptuous palace in a town of Kiang-si; and the superstitious confidence of the people attracts an immense number thither from all parts of the empire. Some arrive in order to be cured of diseases, others to get an insight into futurity. The impostor distributes to them small bits of paper filled with magical characters; and the ignorant wretches depart well satisfied, without grudging the expence of their journey, though ever so long.

A still more pernicious and more widely diffused sect is that of the idol *Fo*, which came originally from India. The *Tao-ffe* had promised to the brother of one of the emperors of China to introduce him to a communication with spirits. The credulous prince having heard of a great spirit named *Fo*, who resided in India, prevailed on his brother to send an embassy thither. On the arrival of the ambassadors, however, they could find only two worshippers of this deity, both of whom they brought to China. Several images

103
Of the worshippers of
Fo.

of

China.

of Fo were also collected at the same time; and these, together with some canonical books of the Indians, were placed on a white horse, and carried in procession to the imperial city.

This superstition was introduced into China about the 65th year of the Christian æra, and soon made vast progress. One of its principal doctrines is that of the metempsychosis, or transmigration of souls, of which M. Grosier thinks he was the inventor, and that Pythagoras, who travelled into several parts of India, had borrowed the doctrine from him. The account given of him by the bonzes is, that finding himself, at the age of 70, oppressed with infirmities, he called his disciples together, and told them he was unwilling to leave the world without communicating the secret and hidden mysteries of his doctrine; which were, in short, that all things had proceeded from a vacuum and nothing, and to that they must return. This doctrine produced a corresponding mode of action, or rather of inaction, in those who believed it: for thus the great happiness of man was made to consist in absolute annihilation; and therefore the nearer he could bring himself to this state during life, the happier he was supposed to be.

The common doctrine, however, which admits of a distinction between good and evil, finds more profelytes among the vulgar, whose situation in life will not allow them to spend their time in perpetual idleness. According to this, the righteous will be rewarded and the wicked punished after death. They say also, that the god Fo came to save mankind, and to expiate their sins; and that he alone can procure them a happy regeneration in the life to come. Five precepts are likewise inculcated on those who adopt this doctrine: 1. Not to kill any living creature. 2. Not to take away the goods of another. 3. Not to pollute themselves by uncleanness. 4. Not to lie; and, 5. Not to drink wine. Above all, they recommend to them to perform acts of mercy, to treat their bonzes well, build temples, &c.

The doctrine of metempsychosis has introduced into China an infinite number of idols, who are all worshipped on the supposition that the spirit of Fo has transmigrated into the animals they represent. These idols, however, seem not to be worshipped with great sincerity; but, like the images of saints in the more superstitious countries of Europe, are beaten and thrown in the dirt when their votaries happen not to obtain their desires, which they impute to the obstinacy or weakness of the idol. Nay, M. Grosier gives an account of one man, who having ineffectually paid a sum of money to the bonzes of a certain idol for the cure of his daughter, brought a formal accusation against the idol itself; and in spite of all that the bonzes could say in its behalf, got its worship suppressed throughout the province.

104
Bad character of the bonzes.

The bonzes of China are represented as a most avaricious and hypocritical race of men, ready to practise every kind of villany, and even to subject themselves to the most intolerable tortures, in order to obtain money from the compassion of the public when they cannot get it in any other way; and an edict of one of the emperors is cited by M. Grosier, by which great numbers of their religious houses were suppressed. In

China.

order to perpetuate their sect, they purchase young children, whom they take care to instruct in all the mysteries and tricks of their profession; but excepting this, they are in general very ignorant, and few of them would be able to give any tolerable account of the tenets of their own sect. They are not subject to a regular hierarchy, but acknowledge superiors among them whom they call grand bonzes, who have the first place in all religious assemblies at which they happen to be present; and great profit is derived from certain religious clubs, both of men and women, at which the bonzes are always called to assist. Their wealth is likewise augmented by pilgrimages to certain places where there are temples more or less revered, and where a multitude of absurd ceremonies are performed. These bonzes, as may be easily imagined, are inveterate enemies to the progress of Christianity, telling the most absurd stories concerning the missionaries; as that they pluck out the eyes of their converts to construct telescopes with, &c. The literati, however, and the more sensible part of the nation, hold them in the greatest contempt.

We shall conclude this detail of the Chinese religion with giving an account of one other superstition which seems peculiar to the nation. It is named *fong-choui*, which signifies wind and water. By this they mean the lucky or unlucky situation of a house, burying-place, &c. If any imprudent person has built a house close to that of a Chinese, in such a manner that the angle formed by its roof flanks the wall or roof of the former house, the proprietor ever after lives in terror of utter ruin and destruction from the malignant influence of that angle. An implacable hatred instantly commences betwixt the two families, and often gives rise to a law-suit, which furnishes matter of discussion for some of the superior tribunals. If no redress can be had at law, however, the Chinese is then reduced to the necessity of erecting, on the top of his house, an enormous image of a dragon, or some other monster, with its mouth gaping towards the angle, and, as it were, threatening to swallow it up; after which the apprehensions of the proprietor begin to subside, and tranquillity is restored to the family. In this manner the governor of *Kien-tchang* secured himself from the influence of the church of the Jesuits, which, being built on an eminence, overlooked his palace. Not depending, however, entirely on the good offices of his tutelary dragon, he also took the wise precaution of altering his principal apartments, and raising, at the distance of 200 paces from the church, a kind of large facade three stories high. But unluckily the death of his successor was attributed to this facade; for the mandarin being attacked with a disorder in his breast, which made him spit up a white phlegm, this symptom was thought to be owing to the walls of the facade, which were very white, and which were forthwith painted black. The salutary precaution, however, happened to be taken too late; for the governor died notwithstanding the black colour of the walls.

“ We should never have done (says M. Grosier), were we to relate all the superstitious ideas of the Chinese, respecting the lucky and unlucky situation of houses, the quarter which doors ought to front, and the plan

105
Ridiculous superstition of the *fong-choui*.

China.

plan and day proper for constructing the stoves in which they cook their rice." But the object on which they employ their greatest care is the choice of the ground and situation for a burying-place. Some quacks follow no other profession than that of pointing out hills and mountains which have an aspect favourable for works of that kind. When a Chinese is persuaded of the truth of such information, there is no sum which he would not give to be in possession of the fortunate spot. The greater part of the Chinese are of opinion that all the happiness and misfortunes of life depend upon the *fong-choui*.

106
Jews and
Mahometans
in
China.

A colony of Jews was established in China about the year 206 B. C.; but they are now reduced to a small number of families at Cai-song, the capital of the province of Honan. The Mahometans have multiplied much more than the Jews. It is above 600 years since they first entered the empire, where they have formed different establishments. At first their number was augmented only by marriages; but for some time past they have been more particularly attentive to the extending of their sect and propagating their doctrine. The principal means employed for this purpose are, to purchase a great number of children brought up in idolatry, whom their poor parents are glad to part with; and these they circumcise, and afterwards instruct in the principles of their religion. During the time of a famine which desolated the province of Chang-tong, they purchased more than 10,000 of these children; for whom, when grown up, they procured wives, built houses, and even formed whole villages of them. They are now become so numerous, that in the places where they reside they entirely exclude every inhabitant who does not believe in their prophet, and frequent a mosque.

107
Ceremo-
nies of
marriage.

With regard to the manners of the Chinese, they bear no resemblance to those of any other nation; and, if we may believe their historians, they are the same at this day that they were 4000 years ago. The women are condemned almost to perpetual imprisonment within the precincts of their own houses, and are never seen even by their intended husbands before marriage. He knows nothing of her looks or person but from the account of some female relation or confidant, who in such cases acts the part of match-maker; though, if imposed upon either with regard to her age or figure, he can have recourse to a divorce. The same matrons who negotiate the marriage, also determine the sum which the intended husband must pay to the parents of the bride: for in China a father does not give a dowry to his daughter; it is the husband who gives a dowry to the wife. When the day appointed for the marriage is arrived, the bride is placed in a chair or close palanquin, the key of which is committed to the care of a trusty domestic, who must deliver it to none but the husband. The latter, richly dressed, waits at his gate for the arrival of the procession. As soon as it approaches, the key is put into his hands; he eagerly opens the chair, and for the first time perceives his good or bad fortune. If he is contented with his new spouse, the bride descends and enters the house, where the marriage is concluded by feasting and merriment as in other countries; but if the bridegroom is very much disappointed, he suddenly shuts the chair,

and sends the bride home to her relations. To get rid of her in this manner, however, costs a sum equal to what he originally gave in dowry to obtain her.

The Chinese women, even of the first rank, seldom quit their apartment, which is situated in the most retired part of the house, and in which they are secluded from all society but that of their domestics. The book of ceremonies requires that there should be two apartments in every house; the exterior one for the husband, the interior for the wife. They must even be separated by a wall or wooden partition, the door of which is carefully guarded; nor is the husband at liberty to enter the wife's apartment, or she to quit it, without sufficient reason. According to the same book, the prattling and loquacity of a woman are reckoned sufficient grounds for a divorce. A woman, however, cannot be divorced on any account, if she loses her parents after marriage, or if she has worn three years mourning for the loss of her husband, father, or mother.

A widow of any rank above the common, who has children, seldom enters a second time into the marriage state, though those of the ordinary rank generally do. The poorer sort are not at liberty to follow their own inclination; but are sold for the behoof of the parents of the deceased. As soon as the bargain is concluded, a couple of porters bring a chair, which is guarded by a number of trusty people. In this the widow is shut up, and thus conducted to her new husband.

"Masters (says Mr Grosier), for the most part, are very desirous of promoting marriage among their slaves, whatever Mr *Pau* may say; who, without any foundation, has ventured boldly to assert the contrary. They have even very strong motives to induce them to encourage these marriages; the children produced by them are still their slaves; and besides their becoming new property to them, the fathers and mothers are thus more strongly attached to their service."

Concubinage is tolerated in China, though not authorized by any law. This privilege is granted only to the emperor, the princes of the blood, and mandarins; and none but the emperor is permitted to have more than one. The common people generally avail themselves of the toleration granted them in this respect, and will have two or three concubines if they can afford it. They are, however, careful to excuse themselves as well as they can to their wives in this respect, pretending only a desire of having many children, and a number of women to attend their wives. Others, desirous of having a male child, which perhaps their lawful wife cannot have, take a concubine for this reason only, and dismiss her as soon as their wishes are accomplished: they then permit her to marry whom she pleases, and frequently even provide a husband for her themselves. These concubines are almost all procured from two cities named *Tang-tcheou* and *Sou-tcheou*, where they are educated, and taught singing, dancing, music, and every accomplishment suitable to women of quality, or which can render them agreeable and pleasing. The greater part of them are purchased in other places, to be again disposed of; and this is the principal branch of trade carried on by these two cities. Unlawful intrigues are seldom heard of in China. Whoever seduces the wife of another

109
Education
of children.

From the accounts we have of the education of children in China, one might be apt to conclude, that, instead of being the ignorant superstitious race already described, they ought to be the most intelligent people in the world. The book of ceremonies directs the education of a child to commence as soon as it is born, and describes exactly the qualities which its nurse ought to have. She must speak little, adhere strictly to truth, have a mild temper, behave with affability to her equals, and with respect to her superiors. The child is taught to use the right hand as soon as it can put its hand to its mouth, and then it is weaned. At six years of age, if a male, he is taught the numbers most in use, and made acquainted with the names of the principal parts of the world; at seven, he is separated from his sisters, and no longer allowed to eat with them, nor to sit down in their presence; at eight, he is instructed in the rules of good breeding and politeness; at nine, he studies the kalendar; at ten, he is sent to a public school, where he learns to read, write, and cast accounts; from 13 to 15 he is taught music, and every thing that he sings consists of moral precepts. It was formerly the custom, that all the lessons designed for the Chinese youth were in verse; and it is to this day lamented, that the same custom is not followed, as their education has since been rendered much more difficult and laborious.

At the age of 15, the Chinese boys are taught to handle the bow and arrow, and to mount on horseback; at 20 they receive the first cap, if they are thought to deserve it, and they are permitted to wear silk dresses ornamented with furs; but before that period they are not allowed to wear any other thing than cotton.

Another method of initiating children into the principles of knowledge in this empire is, by selecting a number of characters expressive of the most common objects, engraving or painting them separately on some kind of substance, and, under the thing represented, putting the name, which points out to the children the meaning of the word.

As the Chinese have no proper alphabet, they represent almost every thing by different characters. The labour of their youth, therefore, is intolerable; being obliged to study many thousand characters, each of which has a distinct and proper signification. Some idea of their difficulties may be obtained from what we are told by F. Martini, who assures us, that he was under the necessity of learning 60,000 different characters before he could read the Chinese authors with tolerable ease.

The book first put into the hands of the Chinese children is an abridgment, which points out what a child ought to learn, and the manner in which he should be taught. This volume is a collection of short sentences, consisting of three or four verses each, all of which rhyme; and they are obliged to give an account in the evening of what they have learned in the day. After this elementary treatise, they put into their hands the four books which contain the doctrines of Confucius and Mencius. The sense and meaning of the work is never explained to them until they have got by heart all the characters, that is to say, the words in the

N^o 78.

book; a method no doubt inconceivably disgusting, and calculated utterly to destroy the genius of a boy, if he has any. While they are getting these characters by heart, indeed, they are likewise employed in learning to form them with a pencil. For this purpose they are furnished with large leaves of paper, on which are written or printed with red ink very big characters; and all they are required to do is to cover those red characters with black ink, and to follow exactly their shape and figure; which insensibly accustoms them to form the different strokes. After this they are made to trace other characters, placed under the paper on which they write. These are black, and much smaller than the other. It is a great advantage to the Chinese literati to be able to paint characters well; and on this account they bestow great pains in forming the hands of young people. This is of the utmost consequence to literary students in the examinations which they are obliged to undergo before they can be admitted to the first degree. Du Halde gives a remarkable instance, viz. that "a candidate for degrees having, contrary to order, made use of an abbreviation in writing the character *ma*, which signifies an horse, had the mortification of seeing his composition, though in other respects excellent, rejected merely on that account; besides being severely rallied by the mandarin, who told him that a horse could not walk unless he had all his legs."

After the scholar has made himself master of the characters, he is then allowed to compose; but the subject of his composition is pointed out to him only by one word. Competitions are likewise established in China, but most of them are of a private nature. Twenty or thirty families, who are all of the same name, and who consequently have only one hall for the names of their ancestors, agree among themselves to send their children twice a month to this hall in order to compose. Each head of a family in turn gives the subject of this literary contest, and adjudges the prize; but this costs him a dinner, which he must cause to be carried to the hall of competition. A fine of about ten pence is imposed on the parent of each scholar who absents himself from this exercise.

Besides these private competitions, every student is obliged to compete at least twice a-year under the inspection of an inferior mandarin of letters, styled *Hio-kouan*. It frequently happens also, that the mandarins of letters order these students to be brought before them, to examine the progress they have made in their studies, to excite a spirit of emulation among them, and make them give such application as may qualify them for any employment in the state. Even the governors of cities do not think it below their dignity to take this care upon themselves; ordering all those students who reside near them to appear before their tribunal once a month: the author of the best composition is honoured with a prize, and the governor treats all the candidates on the day of competition at his own expence. In every city, town, and village in China, there are schoolmasters who teach such sciences as are known in that country. Parents possessed of a certain fortune provide masters for their children, to attend and instruct them, to form their minds to virtue, and to initiate them in the rules of good breeding and the accustomed ceremonies, as well as to make them ac-

5

quainted

China.

China.

quainted with the laws and history, if their age will admit. These masters have for the most part attained to one or two degrees among the literati, and not unfrequently arrive at the first employments of the state.

The education of the Chinese women is confined to giving them a taste for solitude, and accustoming them to modesty and silence; and, if their parents are rich, they are likewise instructed in such accomplishments as may render them agreeable to the other sex.

110
Dress.

There is little distinction in China between the ordinary dress of men and women. Rank and dignity are distinguished by certain accessory ornaments; and the person would be severely chastised who should presume to assume them without being properly authorised. The dress in general consists of a long vest which reaches to the ground. One part of this vest, viz. that on the left side, folds over the other, and is fastened to the right by four or five small gold or silver buttons, placed at a little distance from one another. The sleeves are wide towards the shoulder, growing narrower as they approach the wrist, where they terminate in the form of a horse shoe, covering the hands entirely, and leaving nothing but the ends of the fingers to be seen. Round their middle they wear a large girdle of silk, the ends of which hang down to their knees. From this girdle is suspended a sheath, containing a knife and two of those small sticks which they use as forks. Below this robe they wear a pair of drawers, in summer made of linen, and in winter of satin lined with fur, sometimes of cotton, and in some of the northern provinces of skins. These are sometimes covered with another pair of white taffety. Their shirts are always very short and wide, of different kinds of cloth, according to the season. Under these they wear a silk net to prevent it from adhering to the skin. In warm weather they have their necks always bare; when it is cold, they wear a collar made of silk, fable, or fox's skin, joined to their robe, which in winter is trimmed with sheep's skin, or quilted with silk and cotton. That of people of quality is entirely lined with beautiful fable skins brought from Tartary, or with the finest fox's skin, trimmed with fable; and in the spring it is lined with ermine. Above their robe they wear also a kind of fur-tout with wide sleeves, but very short, which is lined in the same manner. The emperor and princes of the blood only have a right to wear yellow; certain mandarins have liberty to wear satin of a red ground, but only upon days of ceremony; in general they are clothed in black, blue, or violet. The common people are allowed to wear no other colours but blue or black; and their dress is always composed of plain cotton cloth.

111
Chinese
obliged by
the Tartars
to cut off
their hair.

Formerly the Chinese were at great pains to preserve their hair; but the Tartars, who subdued them, compelled them to cut off the greater part of it, and to alter the form of their clothes after the Tartar fashion. This revolution in dress was not effected without bloodshed, though the conqueror at the same time adopted in other respects the laws, manners, and customs of the conquered people. Thus the Chinese are painted as if bald, but they are not so naturally; that small portion of hair which they preserve behind, or on the tops of their heads, is all that is now allowed them. This they wear very long, and plait like a tail. In summer they wear a kind of cap shaped like an invert-

VOL. IV. PART II.

ed cone, lined with satin, and covered with ratan or cane very prettily wrought. The top terminates in a point, to which they fix a tuft of red hair, which spreads over it, and covers it to the brims. This hair grows between the legs of a kind of cow, and is capable of taking any colour, especially a deep red. This ornament is much used, and any person who chooses may wear it.

The mandarins and literati wear a cap of the same form as the foregoing, only it is lined with red satin, and covered on the outside with white. A large tuft of the finest red silk is fixed over it, which is suffered to hang down or wave with the wind. People of distinction generally use the common cap when they mount on horseback or during bad weather; being better calculated to keep off rain, and shelter those who wear it from the rays of the sun. For winter they have another cap bordered with fable, ermine, or fox's skin, and ornamented with a tuft of silk like the former. In these fur-trimmings they are very curious, sometimes expending 40 or 50 ounces of silver upon them.

The Chinese people of rank never go abroad without boots made of satin or some other silk, and sometimes of cotton, but always dyed. They have neither heel nor top, and are made to fit the foot with the greatest exactness. When they travel on horseback, however, they have others made of the skin of a cow or horse made very pliable. Their boot-stockings are of silk stuff, quilted and lined with cotton, reaching above the top of their boot, and ornamented with a border of velvet or cloth. In summer they wear a cooler kind, and in their houses a sort of slippers made of silk stuff. The common people are contented with black slippers made of cotton cloth. The fan is also a necessary appendage of the Chinese dress, and is reckoned equally necessary with the boots.

The dress of the women consists of a long robe quite close at top, and long enough to cover even their toes, with sleeves so long that they would hang down upon the ground, did they not take care to tuck them up; but their hands are seldom seen. The colour of their dresses is entirely arbitrary, but black and violet are generally chosen by those advanced in life. The young ladies, like those of Europe, make use of paint to give a bloom to their complexions; but this, though not the same with the kind used in Europe, agrees with it in the effect of soon wrinkling the skin. Their general head-dress consists in arranging their hair in several curls, among which are interspersed small tufts of gold or silver flowers. According to Du Halde, some of them ornament their heads with the image of a fabulous bird, concerning which many stories are told. This is made of copper or silver gilt, its wings extended and lying pretty close to the head-dress, embracing the upper part of their temples, while the long spreading tail forms a kind of plume on the top of the head. Its body is directly over the head, and the neck and bill hang down, the former being joined to the body by a concealed hinge, in order that it may play freely, and move about on the least motion of the head. The whole bird adheres to the head by means of the claws, which are fixed in the hair.

Ladies of quality sometimes wear several of these birds made up into a single ornament, the workmanship of which is very expensive. Young ladies wear also a

China.

China.

crown made of pasteboard, the fore-part of which rises in a point above the forehead, and is covered with jewels. The rest of the head is decorated with natural or artificial flowers, among which small diamond pins are interspersed. The head-dress of the ordinary class of women, especially when they are advanced in years, consists only of a piece of very fine silk wrapped round their heads.

112

Aburd custom of preventing the feet of female infants from growing.

All authors agree, that an absurd custom prevails throughout China of confining the feet of female infants in such a manner that they are never allowed to grow to near their full size. The smallness of their feet is accounted such a valuable beauty, that the Chinese women never think they can pay too dear for it. As soon therefore as a female infant is born, the nurse wraps up its feet in very tight bandages; and this torture must be endured until their feet have ceased to grow. So prevalent is the force of custom, however, that as the child grows up she voluntarily submits to new tortures in order to accomplish the purpose more effectually. Thus the Chinese women are deprived almost entirely of the use of their feet; and are scarce able to walk, in the most awkward hobbling manner, for the shortest space. The shoe of a full grown Chinese woman will frequently not exceed six inches.

The Chinese use white as the colour proper for mourning; and though a son cannot wear this while his father and mother are alive, he can use no other for three years after their death; and ever afterwards his clothes must be of one colour. The law has forbidden the use of silks and furs to children; and has even prescribed the time when they are first to wear a cap. This is put upon their heads by the master of ceremonies himself, who addresses them in the following manner: "Consider that you now receive the dress of those who have attained to maturity, and that you cease to be children; renounce therefore all childish thoughts and inclinations, assume a grave and serious deportment, apply with resolution to the study of virtue and wisdom, and endeavour to merit a long and happy life." "This ceremony (says M. Grosier), which may appear trifling, is attended with the happiest effects. The Chinese give a kind of importance to every thing which can inspire youth with a taste for morality and a love of good order. It might be useful to mankind at every fixed epocha of their lives, to remind them of those new duties imposed by each successive change; but, by uniting the solemnity of a public ceremony to this instruction, it will make a deeper impression, and remain much longer imprinted on their memories."

113

Excessive ceremoniousness of the Chinese.

Nothing can appear more irksome to an European than the multitude of ceremonies used on all occasions by the Chinese. An invitation to an entertainment is not supposed to be given with sincerity until it has been renewed three or four times in writing. A card is sent on the evening before the entertainment, another on the morning of the appointed day, and a third when every thing is prepared and the guests ready to sit down to the table. The master of the house always introduces his guests into the hall, where he salutes them one after another. He then orders wine to be brought him in a small cup made of silver, porcelain, or precious wood, and placed upon a small varnished salver. He lays hold of it with both his hands,

makes a bow to all the surrounding guests, and advances towards the fore-part of the hall, which generally looks into a large court. He there raises his eyes and the cup towards heaven; after which he pours the wine on the ground. He afterwards pours some wine into a silver or porcelain cup, makes a bow to the most considerable person in company, and then goes to place the cup on the table before him; for in China every guest has a table for himself. The person for whom he intends this honour, however, generally saves him the trouble of placing the cup; calls for wine in his turn, and offers to place the cup on the master's table, who endeavours to prevent him; with a thousand apologies and compliments according to the rules of Chinese politeness. A superior domestic conducts the principal guest to an elbow chair covered with rich flowered silk, where the stranger again begins his compliments, and begs to be excused from sitting in such an honourable seat, which nevertheless he accepts of; and all the rest of the guests do the same, otherwise the ceremonial would be gone through with each of them. The entertainment is concluded by some theatrical representations, accompanied with the music of the country; which, however, would give but little pleasure to an European. Besides the guests, a certain number of people are admitted into the court in order to behold these theatrical representations; and even the women are allowed to view them through a wicket, contrived so that they may behold them without being seen themselves.

The entertainments of the Chinese are begun, not by eating, but by drinking; and the liquor they drink must always be pure wine. The intendant, or *maitre de hotel*, falling down on one knee, first invites the guests to take a glass; on which each of them lays hold, with both hands, of that which is placed before him, raising it as high as his forehead, then bringing it lower down than the table, and at last putting it to his mouth: they all drink together, and very slowly, taking three or four draughts. While they are drinking, the dishes on each of the tables are removed, and others brought in. Each of the guests has twenty-four set before him in succession; all of them fat, and in the form of ragouts. They never use knives in their repasts; and two small-pointed sticks, ornamented with ivory or silver, serve them instead of forks. They never begin to eat, however, until they are invited by the *maitre de hotel*; and the same ceremony must be gone through every time they are going to take a cup of wine or begin to a new dish. Towards the middle of the entertainment the soup is brought in, accompanied with small loaves or meat-pies. These they take up with their small sticks, steep them in the soup, and eat them without waiting for any signal or being obliged to keep time with the rest of the guests. The entertainment, however, continues in other respects with the utmost formality until tea is brought in; after which they retire from table and amuse themselves in another hall, or in the garden for a short time, until the desert be brought in. This, like the entertainment itself, consists of 24 dishes, which are made up of sweatmeats, fruits differently prepared, hams and salted ducks which have been baked or dried in the sun, with shell and other kinds of fish. The same ceremonies which preceded the repast are now renewed,

China.

China.

renewed, and every one sits down at the same place he occupied before. Larger cups are then brought in, and the master invites the guests to drink more freely.

These entertainments begin towards evening, and never end till midnight. A small sum of money is given to the domestics; when every one of the guests goes home in a chair preceded by several servants, who carry large lanthorns of oiled paper, on which are inscribed the quality, and sometimes the name, of the master. Without such an attendance they would be taken up by the guard; and the day following they never fail to return a card of thanks to the officer.

Their method of drinking tea is not like that of other nations. A small quantity of bohea, sufficient to tinge the water and render it palatable (for they drink no green), is taken in the morning, and thrown into a vessel adapted to the number in family. This stands till milk warm; in which state it is kept the whole day, and a cup drank now and then without sugar or milk, in order to exhilarate the spirits when exhausted by fatigue; and if a stranger call by accident, or a visitor by appointment, the first thing presented, after the usual ceremonies of meeting, is a very small pipe filled with tobacco of their own growth and a cup of the tea already mentioned, or of some fresh made of better quality, together with sweetmeats, &c. Tea is the daily beverage in China, and is drank by all ranks of people.

Some change has been made in the ceremonial of the Chinese by the Tartar conquest, and some new dishes also introduced by the same means; and here M. Grosier observes, that the Tartars are much better cooks than the Chinese. All their dishes are highly seasoned; and by a variation in the proportions of their spiceries, they are able to form a variety of dishes out of the same materials. None of their viands, however, are more esteemed than stags sinews, and the nests of a particular species of birds, which have the property of giving a most agreeable relish to whatever is mixed with them. Other dishes are introduced at these repasts, which would be accounted very disagreeable with us; such as the flesh of wild horses, the paws of a bear, and the feet of several wild animals. The greater part of these provisions are brought preserved in salt from Siam, Camboya, and Tartary.

114
Chinese
wines.

The wines of China have no resemblance to ours either in taste or quality, being procured from rice and not from the vine. A particular kind of rice is employed for making them, and the grain is steeped for 20 or 30 days in water, into which ingredients of a different nature are successively thrown: they afterwards boil it; and as soon as it becomes dissolved by the heat, it immediately ferments, and throws up a vaporous scum not unlike new wine. A very pure liquor is found under this scum, which is drawn off and put into vessels well glazed: From the remaining lees an inflammable spirit is made, little inferior, and sometimes even superior, to the European. Another kind of wine is used by the Chinese, or rather Tartars, called *lamb-wine*. It is very strong, and has a disagreeable smell; and the same may be believed of a kind of spirit distilled from the flesh of sheep; though this last is sometimes used by the emperors.

These entertainments exceed the bounds of ordinary repasts; the Chinese being naturally sober, and those in easy circumstances living chiefly on pork, for which

China.

reason a great number of hogs are bred in the country. Their flesh is much easier of digestion, and more agreeable to the taste, than those of Europe. The Chinese hams are in high estimation. The common people live very poorly; being satisfied, in time of scarcity, with the flesh of dogs, horses, cats, and rats, which last are sold publicly in the streets.

There are several public festivals annually celebrated in China. One is that already mentioned, in which the emperor tills the ground with his own hands. This is also celebrated on the same day throughout the empire. In the morning the governor of every city comes forth from his palace crowned with flowers, and enters his chair amidst the noise of different instruments which precede it; a great number of people attending, as is usual on all such occasions. The chair is surrounded by litters covered with silk carpets, on which are represented either some illustrious persons who have supported and encouraged agriculture, or some historical painting on the same subject. The streets are hung with carpets, triumphal arches are erected at certain distances, lanthorns every where displayed, and all the houses illuminated. During the ceremony a figure resembling a cow, made of baked earth, with gilt horns, is carried in procession, and of such enormous magnitude that 40 men are scarce sufficient to support it. A child follows with one foot naked and the other shod, who is called the *spirit of labour and diligence*, and keeps continually beating the image with a rod to make it advance. Labourers, with their implements of husbandry, march behind; and the procession is closed by a number of comedians and people in masks. The governor advances towards the eastern gate, and returns in the same manner. The cow is then stripped of its ornaments, a prodigious number of earthen calves taken from its belly and distributed among the people; after which the large figure is broken in pieces and distributed in the same manner. The ceremony is ended by an oration in praise of agriculture, in which the governor endeavours to excite his hearers to the practice of that useful art.

Other two festivals are celebrated in China with still more magnificence than that above described. One of them is at the commencement of the year; the other is called the *feast of lanthorns*. During the celebration of the former, all business, whether private or public, is suspended, the tribunals are shut, the posts stopped, presents are given and received, and visits paid. All the family assemble in the evening, and partake of a feast to which no stranger is admitted; though they become a little more sociable on the following day.

The feast of lanthorns ought to take place on the 15th day of the first month, but usually commences on the evening of the 13th, and does not end till that of the 16th. At that time every city and village, the shores of the sea, and the banks of all the rivers, are hung with lanthorns of various shapes and sizes; some of them being seen in the courts and windows of the poorest houses. No expence is spared on this occasion; and some of the rich people will lay out eight or nine pounds sterling on one lanthorn. Some of these are very large, composed of six wooden frames either neatly painted or gilt, and filled up with pieces of fine transparent silk, upon which are painted flowers, animals, and human figures; others are blue, and made of a transparent kind of horn. Several lamps, and a

China.

great number of wax-candles, are placed in the inside: to the corners of each are fixed streamers of silk and satin of different colours, with a curious piece of carved work on the top. They are likewise acquainted with our magic lanthorn, which they sometimes introduce in this festival. Besides this, they have the art of forming a snake 60 or 80 feet in length, filled with lights from one end to the other; which they cause twist itself into different forms, and move about as if it was a real serpent. During the same festival all the varieties of the Chinese fire-works, so justly admired, and which, some time ago at least, surpassed every thing of the kind that could be done in Europe, are exhibited.

1:6
Magni-
fice-
nce of
the vice-
roys.

Every public ceremony in China is carefully rendered as striking as possible. A viceroy never quits his palace but with a royal train, dressed in his robes of ceremony, and carried in a chair elegantly gilt, which is borne upon the shoulders of eight domestics; two drummers marching before the guards, and beating upon copper basons to give notice of his approach. Eight other attendants carry standards of wood varnished, upon which are inscribed in large characters all his titles of honour. After these come 14 flags with the symbols of his office; such as the dragon, tyger, phoenix, flying tortoise, &c. Six officers follow, each bearing a piece of board in shape like a large shovel, on which are written in large golden characters the qualities of the mandarin himself: two others carry, the one a large umbrella of yellow silk, and the other the cover in which the umbrella is kept. The first guards are preceded by two archers on horseback; the latter are followed by others armed with a kind of weapons composed of hooked blades, fixed perpendicularly to long poles ornamented with four tufts of silk, placed at a small distance above one another. Behind these are two other files of soldiers, some of whom carry large maces with long handles; others iron maces in the shape of a snake; others are armed with huge hammers; while those behind them carry long battle-axes in the form of a crescent: others follow, who have battle-axes of another kind; and behind these are some with the hooked weapons already described.

Behind these come soldiers armed with triple-pointed spears, arrows, or battle-axes; having in front two men who carry a kind of box containing the viceroy's seal. Then come two other drummers to give notice of his approach. Two officers follow, having on their heads felt-hats, adorned with plumes of feathers, and each armed with a cane to recommend regularity and good order to the surrounding multitude. Two others bear maces in the form of gilt dragons. These again are followed by a number of magistrates and officers of justice; some of whom carry whips or flat sticks, while others have chains, hangers, and silk scarfs. Two standard-bearers and a captain command this company, which immediately precedes the governor. His chair is surrounded by pages and footmen, and an officer attends him who carries a large fan in form of a screen: he is followed by several guards differently armed, together with ensigns and other officers, who are also followed by a great number of domestics all on horseback, carrying various necessaries for the use of the mandarin. If he marches in the night-time, instead of flambeaux, as are customary in Europe, large lanthorns, exceedingly pretty, are carried before him;

on the transparent part of which are written, in very conspicuous characters, his quality, titles, and rank, as mandarin. These are also intended to give notice to the passengers to stop, and to those who are sitting to rise up with respect; for whoever neglects either the one or the other is sure to receive a severe bastinading.

The emperor marches with still more magnificence, in proportion to his superior quality. The trumpets used in his procession are about three feet long, eight inches in diameter at the lower extremity, and pretty much resembling a bell in shape: their sound is peculiarly adapted to that of the drums. His cavalcade is closed by 2000 mandarins of letters and as many of arms. Sometimes the great mandarins, as well as the emperor, travel in barks. Their attendance is then somewhat different, but the magnificence almost the same. The honours paid to a viceroy who has governed a province with equity are exceedingly great on his departure from it. He has scarcely left the capital of the province when he finds on the highway, for the space of two or three leagues, tables ranged at certain distances, each of which is surrounded with a long piece of silk that hangs down to the earth. On these wax candles are placed even in the open day; perfumes are burnt upon them; and they are loaded with a profusion of victuals and various kinds of fruit, while tea and wine are prepared for him on others. The people throw themselves on their knees as he passes, and bow their heads even to the earth; some shed tears, or pretend to do so; some present him wine and sweetmeats; others frequently pull off his boots and give him new ones. These boots, which he has perhaps used only for a moment, are considered as a valuable monument: those first taken off are preserved in a cage over the gate of the city; the rest are carefully kept by his friends.

Hitherto our author, M. Grosier, has seemed inclined to give a favourable idea of the Chinese, and to cause us look upon them as many degrees superior to ourselves in the practice of virtue and morality; but when he comes to give an account of their dealings in trade, he is then obliged to confess that they are as dishonest and knavish a race as any that exist. "The most frequented fairs of Europe (says he) afford but a faint idea of that immense number of buyers and sellers with which the large cities of China are continually crowded. We may almost say, that the one half are employed in over-reaching the other. It is, above all, against strangers that the Chinese merchants exercise, without any sense of shame, their insatiable rapacity. Of this F. du Halde gives a striking example, which might be supported by many others: 'The captain of an English vessel bargained with a Chinese merchant at Canton for several bales of silk, which the latter was to provide against a certain time. When they were ready, the captain went with his interpreter to the house of the Chinese merchant to examine whether they were sound and in good condition. On opening the first bale, he found it according to his wish, but all the rest were damaged and good for nothing. The captain on this fell into a great passion, and reproached the merchant in the severest terms for his dishonesty. The Chinese, after having heard him for some time with great coolness, replied, 'Blame, Sir, your knave of an interpreter: he assured me that you would not inspect the bales.'

"The lower class of people are, above all, very dexterous

117
Knavish
disposition
of the Chi-
nese.

China.

terous in counterfeiting and adulterating every thing they sell. Sometimes you think you have bought a capon, and you receive nothing but skin; all the rest has been scooped out, and the place so ingeniously filled, that the deception cannot be discovered till the moment you begin to eat it. The counterfeit hams of China have been often mentioned. They are made of a piece of wood cut in the form of a ham, and coated over with a certain kind of earth which is covered with hog's skin. The whole is so curiously painted and prepared, that a knife is necessary to detect the fraud. Mr Osbeck relates, that having one day observed a blind man carrying about for sale some of those trees called by the Chinese *Fo-kei*, he purchased one, which to appearance had fine double red and white flowers; but on closer examination, he found that the flowers were taken from another tree, and that one calyx was so neatly fitted into the other, with nails made of bamboo, that he should scarcely have discovered the deceit, had not the flowers begun to wither. The tree itself had buds, but not one open flower.

"The robbers in China signalize themselves also by their dexterity and ingenuity, which they display in their profession. They seldom have recourse to acts of violence, but introduce themselves into a house either privately or by forming some connection with the family. It is as difficult in China to avoid robbery as it is to apprehend the criminal in the fact. If we are desirous of finding among the Chinese openness of temper, benevolence, friendship, and, lastly, virtue, we must not seek for it in cities, but in the bosom of the country, among that class of men who have devoted themselves to labour and agriculture. A Chinese rustic often discovers moral qualities which would add a lustre to the character of men of the most exalted rank. It appears that rural life naturally inspires sentiments of benevolence; by continually receiving the gifts of nature, the mind is enlarged, and men are insensibly accustomed to diffuse them to those around them."

The internal commerce of China is much greater than that of all Europe; but its foreign trade is by no means equal to that of any of the grand European powers. Its internal commerce is greatly facilitated by the vast number of canals and rivers with which the country is intersected. The Chinese, however, are not at all fitted for maritime commerce: Few of their vessels go beyond the straits of Sunda; their longest voyages to Malacca extend only as far as Acheen, towards the straits of Batavia, and northward to Japan.

Their commerce with the last mentioned island, considering the articles of exchange which they procure at Camboya or Siam, produces them *cent. per cent.* Their trade with the Manillas brings only about *50 per cent.* Their profit is more considerable about Batavia; and the Dutch spare no pains to invite them to traffic at their settlements. The Chinese traders go also, tho' not very frequently, to Acheen, Malacca, Thor, Patan, and Ligor, belonging to Siam and Cochinchina; from whence they bring gold and tin, together with some objects of luxury for the table. A great obstacle to the foreign commerce of the Chinese is their indifference about maritime affairs, and the bad construction of their vessels. This they themselves acknowledge; but say, that any attempt to remove it would be dero-

gating from the laws, and subverting the constitution of the empire.

The burying-places in China are always situated at a small distance from a city or town, and generally upon some eminence, having pines or cypresses usually planted around them. The form of the tombs is various, according to the different provinces, and the situation of those for whom they are intended. The coffins of the poor are placed under a shade covered with thatch, or inclosed in a small building of brick in the form of a tomb. The tombs of the rich are shaped like a horse-shoe, well whitened, and finished with great taste; but those of the mandarins and people of quality are much more sumptuous and elegant. A vault is first constructed, in which the coffin is shut up; over this vault is raised a pyramid of earth well beat together, about 12 feet in height and 10 in diameter. A layer of lime and sand laid over this earth makes a kind of plaster, which renders the whole very durable and solid; various kinds of trees being planted around it in regular order. Before it is placed a large and long table of white marble, on the middle of which are set a censer accompanied with two vases, and the same number of candlesticks of exquisite workmanship. Besides this, a great number of figures, representing officers, eunuchs, soldiers, saddled horses, camels, lions, tortoises, &c. are ranged round the tombs in different rows; which, F. du Halde assures us, produce a very striking effect.

When a Chinese dies in a province in which he was not born, his children have a right, nay it is their indispensable duty, to transport the body to the burying place of their ancestors. A son, who should be wanting in this respect, would be disgraced, and his name never placed in the hall of his ancestors. This is a vast building, considered as common to all the branches of the same family, and to which they all repair at a certain season of the year. Sometimes they amount to seven or eight thousand persons, whose fortune, dignity, and rank in society, are all very different; but there no distinction of rank is known; age only gives precedence, and the oldest always takes place of all the rest, though he should be the poorest in the company. The distinguishing ornament of this hall is a long table set against the wall, upon which is generally seen the image of one of their ancestors, who has filled some office of distinction in the empire with honour to himself, or who has been rendered illustrious by his talents and abilities. Sometimes it only contains the names of men, women, and children belonging to the family inscribed upon tablets, together with their age, the day of their death, and the dignities they enjoyed at that time. These tablets are ranged in two rows upon steps, and are only about a foot high each. In the spring, and sometimes in the autumn, the relations of the deceased repair to this hall, where the only privilege enjoyed by the richest is that of preparing an entertainment, and treating the whole family at their own expences; but they never allow themselves to taste a bit of any thing until an offering has been first made to their ancestors. This does not, however, excuse them from visiting the real tomb of their ancestors once or twice a year, generally in the month of April. At this time they pluck the weeds and bushes from around the tomb, renew their expressions

119
Funeral ceremonies.

of grief, and conclude by placing upon it wine and provisions, which serve to dine their assistants.

The funeral ceremonies are considered by the Chinese as the most important of any. A few moments after a person has expired, he is dressed out in his richest attire, and adorned with every badge of his dignity; after which he is placed in the coffin. The preparation of a coffin, in which his body may be inclosed after death, is one of the chief objects of attention to a Chinese during his life, and great expence is often thrown out upon it; insomuch that the poor will give all they are worth, and the rich expend a thousand crowns, nay, a son will sell himself for a slave in order to purchase a coffin for his father. Sometimes the coffin, when purchased with all this labour and expence, will remain twenty years useless in the family, and is considered as the most valuable piece of furniture in his possession.

The manner of interment is as follows: First they sprinkle some lime in the bottom of the coffin; then they lay the body in it, taking care to place the head on a pillow, and to add a great deal of cotton, that it may remain more steady, and be prevented from shaking. In this manner the body remains exposed seven days; but the time may be reduced to three, if any weighty reason makes it necessary; and, during this interval, all the relations and friends, who are purposefully invited, come and pay their respects to the deceased, the nearest relations even remaining in the house. The coffin is exposed in the hall of ceremony, which is then hung with white, but some pieces of black or violet coloured silk are here and there interspersed, as well as some other ornaments of mourning. Before the coffin is placed a table, on which stands the image of the deceased, or a carved ornament inscribed with his name; and these are always accompanied with flowers, perfumes, and lighted wax candles.

In the mean time those who enter the hall are accustomed to salute the deceased as if he were still in life. They prostrate themselves before the table, and knock their foreheads several times against the earth; after which they place on the table some perfumes and wax candles provided for the purpose. The salutation which they have made to the deceased is returned by the eldest son accompanied by his brothers. The latter come forth from behind a curtain, which hangs on one side of the coffin, creeping along the ground until they reach the spot where those stand whom they are going to salute; after which, without rising up, they return to the place from whence they came. The women are also concealed behind the same curtain, from whence they every now and then send forth dismal cries.

After a number of ceremonies and invitations, the funeral procession at last commences. A troop of men march in a file, carrying different figures made of paste-board, and representing slaves, lions, tigers, horses, &c. Others follow, marching in two files; some of which carry standards, some flags or censers filled with perfumes; while melancholy and plaintive airs are played by others on different musical instruments. These musicians immediately precede the coffin, which is covered with a canopy, in form of a dome, of violet-coloured silk: its four corners are ornamented with tufts of white silk very neatly embroidered, and covered

at the top with net-work. The coffin is placed on the bottom of this machine, and is carried by 64 men. The eldest son, clothed in a frock of canvas, having his body bent and leaning on a staff, follows near the coffin; and behind him his brothers and nephews, but none of them clothed in canvas. Then come the relations and friends, all clad in mourning, and followed by a great number of chairs covered with white stuff, which contain the wives and female slaves of the deceased. These make great show of sorrow by their doleful cries; but M. Grosier observes, that, in spite of all they can do, the lamentations of the Chinese are so methodical, that an European would be apt to conclude that they were the effects of art rather than the natural effusions of a mind agitated and oppressed with grief. When they arrive at the burying place, the coffin is deposited in a tomb appropriated for it, not far from which there are tables arranged in different halls, and on which the assistants are entertained with great splendor. The entertainment is sometimes followed by fresh marks of homage to the corpse; but these are often changed into thanks to the eldest son; who, however, answers only by signs. But if the deceased was a grandee of the empire, a certain number of his relations never leave the tomb for a month or two. There they reside in apartments purposefully provided for them, and every day renew their marks of grief in company with the children of the deceased. The magnificence of these funeral ceremonies is proportioned to the wealth or dignity of the deceased. That of one of the brothers of the emperor was attended by 16,000 people, each of whom had a particular office assigned him relating to the ceremony.

Mourning continues in China for three years; and during all this time they are obliged to abstain from the use of flesh and wine; nor can they assist at any entertainment of ceremony, or attend any public assembly. At first they are not even permitted to go abroad; and when they do so, they are carried in a chair covered with a white cloth. Sometimes the filial piety of the Chinese is carried to such a length, that they preserve the bodies of their deceased fathers in their houses for three or four years; and those who do so impose also upon themselves a great number of other duties, using no other seat during the day but a stool covered with white serge, and no other bed but a plain mat made of reeds, which is placed near the coffin.

According to M. Grosier, the only diversions of the Chinese are those of hunting and fishing, dancing not being practised, and gaming forbidden by law. Fishing is considered by them rather as an object of commerce and industry than amusement. They catch fish by various methods; using nets in their great fisheries, but lines in the private. In certain provinces also they use a certain kind of bird whose plumage greatly resembles that of a raven, but with a much longer bill, very sharp and hooked. This method of fishing is practised in boats, of which great numbers may be seen on the river about sun-rising, with the fishing-birds perched on their prows. These birds are taught to catch fish almost in the same manner that dogs pursue game. The fishermen, after making several turns with their boats, beat the water strongly with one of their oars. This serves as a signal to the birds, who instantly plunge into the water, and diving, swallow as many small

China.

120

Mourning.

121

Diversions of hunting and fishing.

China.

small fish as they can, repairing immediately afterwards to the boat, and carrying a large one by the middle in their bill. The small ones are prevented from passing into the stomach by a ring placed on purpose to confine its gullet: and thus the fisherman by stroking its neck with the head downwards, makes the bird disgorge all those small fish it has swallowed. When they have done fishing, the rings are taken off, and the birds allowed to feed. When the fish happens to be too large for a single bird, the others have sagacity enough to assist it; one taking it by the tail, another by the head, &c. and thus they transport it to their master.

Another method of fishing, practised only in China, is as follows: They nail a board, about two feet in breadth, which is covered with a white shining kind of varnish, upon the edges of a long narrow boat, from one end to the other. This board is placed in such a manner as to slope almost imperceptibly to the water. It is used only in the night-time, and is always turned towards the moon, that the reflection of light from the luminary may increase the splendor of the varnish. The fish, in sporting, often mistake this varnished board for water; and endeavouring to throw themselves into it, fall into the boat.

The soldiers have a particular method of fishing with a bow and an arrow; the latter of which is fixed to the bow by a string, both to prevent it from being lost, and to enable them to draw out the fish which the arrow has pierced: others make use of tridents to catch large fish which are sometimes found in the mud.

Besides these diversions, the Chinese have some strolling players, but no regular theatres; they have likewise musicians and singers, but no operas, or indeed any public spectacle worthy of notice.

122
Of the Chinese language.

The language of the Chinese is not only very ancient, but, in M. Grosier's opinion, is still spoken as in the most early ages without any variation. His reasons for this opinion are, 1. We do not perceive in history, nor even in the most fabulous traditions, a single fact tending to occasion any doubt of the language spoken by the ancient Chinese being different from that used at present. 2. China has never changed its inhabitants; and if revolutions have occasioned any mixture of new languages, it appears that the ancient language has always been predominant, and that the new settlers have learned and spoken it, as the Marchew Tartars after their conquest. 3. The most intelligent and discerning of the literati agree, that the first chapters of the *Chou-king* were written under the reign of Yao 2300 years before Christ; and in these, several speeches of the first emperors are related word for word; and it is not probable that the language of these princes was different from that of the historian. 4. A compliment paid to Yao by one of his subjects, with the answer of that prince, are still preserved, as well as two songs composed under the same reign. 5. The most ancient inscriptions in China are all in the language spoken throughout the empire at this day. 7. The Chinese have borrowed nothing from other nations; and their attachment to their own customs, and to antiquity, must undoubtedly be very unfavourable to any innovation. The language spoken by the vulgar, indeed, must have undergone some changes; but these may be accounted trivial, affecting only the pronunciation; which indeed appears to be

China.

varied in some few instances. It is certain, however, that the Chinese players act theatrical pieces which were written 1000 years ago, and that these are still understood throughout the empire.

The language of China has no alphabet; all the words which compose it consist of one syllable only, and are very few in number. These always remain the same, and continue monosyllables even when two are joined together, being united in the same manner as the French words *bon* and *jour* are united to form *bon-jour*. These monosyllables never form but one sound. When written by an European, they begin with the letters *ch, tch, f, g, or j, i, b, l, m, n, g, ng, p, s, ts, v, ou*; the final letters being *a, e, i, o, oi, ou, u, l, n, gn*. The middle of Chinese words consists of vowels and consonants producing only one sound, and pronounced always as monosyllables. The whole primary words of the language are in number only about 330, though some dictionaries make them 484. The sense of these words, however, is varied by the accents and changes of the voice in pronouncing them almost *ad infinitum*. Two principal accents are known in China; the *ping*, that is *even*, without elevating or depressing the voice. This is divided into *tsing*, *clear*, and *tcho*, *obscure*; or rather *open* and *mute*. The accent *tsé* is subdivided into *tchang*, sharp, *kiu*, grave, and *jou* re-entering. The tone is *chang* when one raises the voice at the end of a word, as when the negative *no* is pronounced with great emphasis and force; it is *kiu* when one depresses the voice with an air of timidity. When the accent is *jou*, the voice is drawn back as it were into the throat; and the aspiration which takes place on certain words beginning with the letters *c, k, p, t*, still adds to these varieties.

By these differences in pronunciation the signification of the words is totally changed: thus the word *tchu* pronounced by lengthening the *u*, and with a clear tone of voice, signifies master or lord: if it is pronounced in an uniform tone by lengthening the *u*, it signifies *hog*: when pronounced lightly, and with rapidity, it signifies *kitchen*; and when articulated with a strong voice depressed towards the end, it signifies a *pillar*.

By the conjunction and modification of these different monosyllables, a Chinese can express every thing he has occasion for; and it may be easily seen what variety must result from this art of multiplying words. The Chinese language therefore has words expressive of the smallest variation of circumstance, and which cannot be expressed in the European languages without a circumlocution. Thus, instead of the five words, calf, bull, ox, heifer, cow, every time that a cow has a calf she acquires a new name in the language of this empire; and still another when she becomes barren. An ox fed for sacrifice has a particular name, which is changed when he goes to the altar. In like manner, a whole dictionary might be composed of the words that are employed to express the different parts of the emperor's palace, and those that are in a manner consecrated to it; others being employed when the palaces of princes or mandarins are spoken of. Thus the number of their characters are augmented beyond all bounds, so that the greater part of their literati spend all their lives in studying them.

In the Chinese there are four different languages. 1. The *Kou-ouen*, or classical language. This is not spoken

China.

spoken at present, though it is generally believed to have been the language of the early ages. It is so laconic, and the ideas are so crowded, that it is very difficult to be understood; however, the literati, who can read and understand it, are much delighted with it. 2. The *Ouen-tchang* is the language used in compositions where a noble and elevated style is requisite. It is never spoken, but certain sentences and complimentary expressions are sometimes borrowed from it. It approaches near to the laconic brevity and majestic sublimity of the *Kou-ouen*, and is equally proper for every kind of subject, excepting only the ambiguities of metaphysics, and the formal rugged diction used in treating of the abstract sciences.

3. The *Kouan-ha* is the language of the court, of people in office, and of the literati. It admits of synonymous expressions to moderate the brevity of monosyllables; of pronouns and relatives; prepositions, adverbs, and particles; to supply the want of cases, moods, tenses, and numbers, which have place in other languages.

4. *Hiang-tan* is a kind of corrupted language, or provincial dialect, spoken by the lower classes in China; and of which every province, city, and almost every village, has its own. Besides the sense of the words, which is changed in a great variety of places, they are so altered by diversity of pronunciation as to be almost unintelligible.

123
Chinese
writing.

There are five kinds of writing mentioned by the Chinese literati; the most modern of which is a method of tracing out the characters with a pencil. This is difficult, and requires much experience; at any rate, it disfigures the characters greatly, and is therefore only used in the prescriptions of physicians, prefaces to books, and inscriptions of fancy. The tracing of characters with neatness and accuracy, however, as we have already had occasion to observe, is greatly admired in China. They are often preferred to the most elegant painting; and some will give a most exorbitant price for a page of an old book, if it happens to be neatly written. They pay particular attention to well-formed characters even in the most common books; and if any of the leaves happen to fall off, will replace them with the greatest attention. To apply them to any vile purpose, tread them under foot, &c. would be reckoned an unpardonable violation of decency and politeness; nay, it often happens, that workmen, such as masons and joiners, dare not tear a printed leaf of paper fixed to the wall.

124
Of their
poetry.

Punctuation was not formerly used in China, nor are points as yet employed in works of an elevated style, or such as are to be presented to the emperor. Poetry is seldom any object of attention, though the taste for it seems to be pretty general in China. Their versification has its rules, and is no less difficult than that of other nations. Only the most harmonious, energetic, and picturesque words, are to be employed, and they must always be used in the same sense in which they were used by the ancients. Each verse can contain only a certain number of words; all of which must be ranged according to the rules of quantity, and terminate in rhyme. The number of verses in a strophe is not determined; but they must be uniform, and present the same distribution of rhymes. The small number of poetical expressions contained in the Chinese No. 78.

China.

Chinese language has rendered it necessary to extend the poetical licence to a great length in this respect. The Chinese poets are allowed to employ a blank verse in every four. They are acquainted with most kinds of poetry in use among us. They have stanzas, odes, elegies, idylls, eclogues, epigrams, satires, and even *bouts rimes*. The common people have also ballads and songs peculiar to themselves. Some of the most distinguished of the literati have even thought it of importance enough to turn the most celebrated maxims of morality, with the rules of civility, into verse. Their poetry is seldom disgraced by any kind of obscenity; and indeed any such thing would be severely punished by government. That severe attention with which every thing tending to corrupt the morals is watched in China, prohibits not only poems of this kind, but likewise romances of all sorts. The police, however, permits such novels as have an useful tendency, and in which nothing is introduced prejudicial to sound morality. Every author who writes against government is punished with death, as well as all those who have had any hand in the printing or distribution of his works.

The art of making paper and printing have been long known among the Chinese. That kind of paper now in use was first manufactured about 105 years before the Christian æra. Before that period they used cloth, and various kinds of silk stuff, instead of paper; and to this day they still preserve a custom of writing the praises of the dead upon large pieces of silk, which are suspended on one side of the coffin, and carried in funeral processions; and of ornamenting their apartments with maxims and moral sentences written in the same manner. In ages still more early, they wrote with a kind of style upon pieces of bamboo, or even upon plates of metal. The first paper was invented by a mandarin. He took the bark of trees, hemp, and old pieces of silk-stuff, boiling them together until they were reduced to a kind of paste, of which he formed his paper; which by degrees was brought to perfection, and the art of whitening and giving it a lustre found out. A great number of different substances are now used in this empire for making paper; such as the bamboo reed, the cotton shrub, the bark of the plant called *kou-chu*, and of the mulberry tree; hemp, the straw of wheat and rice, parchment, the cods of the silk worm, and several other substances unknown in Europe. In this manufacture the bark of trees and shrubs is used, and the woody substance of the bamboo and cotton tree, after it has been macerated and reduced to a thin paste. Most of the Chinese paper, however, is attended with the disadvantage of being very susceptible of moisture, readily attracts the dust, and worms insensibly get into it: to prevent which inconveniences, it is necessary to beat the books often, and expose them to the sun. That made of cotton is the prettiest, and most used of any. All of them, however, are much softer and smoother than ours; which is absolutely necessary for their method of writing with a pencil, in order that it may run with freedom, which it could not do upon ours. It is formed into sheets of an enormous size; so that it would be no difficult matter to procure from the manufactories of this empire sheets of paper 30 or 40 feet long.

The Chinese ink came originally from Corea; and it was not until the year 900, that they hit upon the method

126
Ink.

China. thod of making it to perfection. The best is made in *Hoei-tcheou* in the province of *Kiangnan*; but its composition is a secret, which the workmen conceal not only from strangers, but from their fellow-citizens. When a Chinese has occasion to write, he places upon his table a piece of polished marble, having a cavity at one of its extremities to contain a little water. In this he dips the end of his cake of ink, and rubs it upon the smooth part of the marble; and as he presses more or less strongly, the liquor acquires a deeper or lighter tinge of black. When he has done writing, the stone is carefully washed; for it would be dishonoured by allowing the least spot to remain. The pencils used in writing are commonly made of the fur of a rabbit, and consequently very soft.

127
Their method of printing.

The Chinese method of printing is exceedingly different from ours; and indeed it would be in a manner impossible to have moveable types for such a number of characters as their language requires. The whole work which they intend to print is therefore engraved upon blocks of wood; and their method of proceeding is as follows. They first employ an excellent writer, who transcribes the whole upon very thin paper. The engraver glues each of the leaves of the manuscript upon a piece of plank made of any hard wood: he then traces over with a graver the strokes of the writing, carves out the characters in relief, and cuts down the intermediate part of the wood. Thus each page of a book requires a separate plank; and the excessive multiplication of these is no doubt a very great inconvenience, one chamber being scarce sufficient to preserve those employed for a single book. The advantages are, that the work is thus free from typographical errors, and the author has no occasion to correct the proofs. Thus also the booksellers in China have a decided advantage over those of Europe, as they are able by this method of printing to throw off copies according to their sale, without running the risk of being ruined by too large an edition. In this method the beauty of the work depends entirely upon the skill of the writer previously employed. The engravers are exceedingly dexterous, and imitate every stroke so exactly, that it is sometimes difficult to distinguish a printed work from one that is only written.

The method of printing in China is not by a press as in Europe, as neither their wooden planks nor their soft paper could sustain so much pressure. They first place the plank level, and then fix it in that position. The printer is provided with two brushes, and, with the hardest, daubs the plank with ink; and one daubing is sufficient for four or five leaves. After a leaf has been adjusted upon the plank, the workman takes the second brush, which is softer than the former, and of an oblong figure, and draws it gently over the paper, pressing it down a little, that it may receive the ink. The degree of pressure is to be regulated by the quantity of ink upon the plank: and in this manner one man is able to throw off almost 10,000 copies a-day. The ink used for printing is different from that formerly described, and which is used in writing. The leaves, on account of the thinness of the paper, are printed only upon one side; on which account each leaf of a book is double, so that the fold stands uppermost, and the opening is towards the back, where it is stitched. Hence the Chi-

VOL. IV. Part II.

nese books are not cut on the edges, but on the back. They are generally bound in grey pasteboard, which is very neat; and those who wish to have them more elegantly done, get the pasteboard covered with satin, flowered taffety, and sometimes with gold and silver brocade. Their books are neither gilt nor coloured on the edges like ours.

The art of manufacturing silk, according to the best authorities, was communicated by the Chinese to the Persians, and from them to the Greeks. The art has been known in this empire from the remotest antiquity; and the breeding of silk-worms and making of silk was one of the employments even of the empresses in very early ages.

The most beautiful silk in the whole empire is that of *Tche-kiang*, which is wrought by the manufactories of Nanking. From these are brought all the stuffs used by the emperor, and such as he distributes in presents to his nobility. A great number of excellent workmen are also drawn to the manufactories of Canton by the commerce with Europe and other parts of Asia. Here are manufactured ribbons, stockings, and buttons. A pair of silk stockings here cost little more than 6s. sterling.

The quantity of silk produced in China seems to be almost inexhaustible; the internal consumption alone being incredibly great, besides that which is exported in the commerce with Europe and the rest of Asia. In this empire all who possess a moderate fortune wear silk clothes; none but the lower class of people wearing cotton stuffs, which are commonly dyed blue. The principal stuffs manufactured by them are plain and flowered gauzes, of which they make summer dresses, damask of all colours; striped and black satins; napped, flowered, striped, clouded, and pinked taffeties; crapes, brocades, plush, different kinds of velvet, and a multitude of other stuffs unknown in Europe. They make particular use of two kinds; one named *touan-tse*, a kind of satin much stronger, but which has less lustre, than that of Europe; the other a kind of taffety, of which they make drawers and linings. It is woven exceedingly close, and is yet so pliable that it may be rumpled and rubbed between the hands without any crease; and even when washed like cotton-cloth, it loses very little of its lustre. They manufacture also a kind of gold brocades, but of such a slight nature, that they cannot be worn in clothes: they are fabricated by wrapping fine slips of gilt paper round the threads of silk.

Porcelain is another great branch of Chinese manufacture, and employs a vast number of workmen. The finest is made in a village called *King-te-ching* in the province of *Kiang-si*. Manufactories have also been erected in the provinces of Fo-kien and Canton, but their produce is not esteemed; and one which the emperor caused to be erected at Peking, in order to be under his own inspection, miscarried entirely.

The Chinese divide their porcelain into several classes, according to its different degrees of fineness and beauty. The whole of the first is reserved for the use of the emperor, so that none of it ever comes into the hands of other persons, unless it happen to be cracked or otherwise damaged in such a manner as to be unworthy of being presented to the sovereign. Among that sent to the emperor, however, there is some porcelain of an

China.

128
Vast quantity of silk produced.

129
Porcelain.

China. inferior quality, which he disposes of in presents. There is some doubt, therefore, whether any of the finest Chinese porcelain was ever seen in Europe. Some value, however, is now put upon the European porcelain by the Chinese themselves.

130
Glas of
little esti-
mation.

The use of glass is very ancient in China, though it does not appear that great value was ever put upon this kind of ware, the art of manufacturing it having been frequently lost and revived again in this empire. They greatly admire the workmanship of the European crystal, but prefer their own porcelain, which stands hot liquors, and is much less liable to be broken. The little estimation in which this substance was held, is even mentioned by their own writers in speaking of the false pearls, mirrors, and other toys which were made in former ages. The remembrance of a very large glass vessel, however, which was made in 627, is still preserved; and of which it was said that a mule could as easily enter it as a gnat could enter a pitcher. In order to transport this monstrous vessel from the place where it was manufactured to the emperor's palace, it was necessary to inclose it in a net, the four corners of which were fixed to four carriages. The same indifference with regard to glass is still entertained by the present emperors; however, a glass-house is established at Peking, where a number of vases and other works are made; and these are so much the more difficult in the execution, as none of them are blown. This manufactory, as well as many others, is considered only as an appendage of the court, destined for the purposes of pomp and magnificence.

131
Medicine.

Most of the Chinese medicine is absolute quackery; their skill in anatomy is not only very limited, but mixed with such a number of falsehoods, as render it in a manner absolutely useless. Their materia medica consists mostly of herbs, of which tea is one. To this they ascribe great and wonderful virtues, especially if it has been gathered on any of the summits of a mountain called *Mong-chan*. The only thing regarding this science, which merits any attention, is the method they are said to possess of discovering whether a man has hanged or drowned himself, or had that violence committed upon him by others. In order to discover this, the body is first taken from the earth, and washed in vinegar. After this a large fire is kindled in a pit dug on purpose, six feet long, three wide, and the same in depth. This fire is continually augmented, until the surrounding earth becomes as hot as an oven; the remaining fire is then taken out, a large quantity of wine is poured into it, and it is covered with a hurdle made of osier twigs, upon which the body is stretched out at full length. A cloth is thrown over both in the form of an arch, in order that the steam of the wine may act upon it in every direction. At the end of two hours the cloth is taken off; and if any blows have been given, they then appear upon the body in whatever state it may be. The Chinese likewise assert, that if the blows given have been so severe as to occasion death, this trial makes the marks appear upon the bones, though none of them should be broken or apparently injured. The wine used in these trials is only a kind of beer made from rice and honey.

133
Of their
music.

With regard to the music of the Chinese, we have the same stories related as of the Greeks and Egyp-

tians, viz. that in former ages the musicians could make brute animals leap at the sound of their instruments. Our author, M. Grosier, indeed, does not quote any Chinese author who asserts that the ancient music could make trees dance, or stones arrange themselves into a city; but he quotes them, asserting, "that the musicians could call down superior spirits of every age from the etherial regions; raise up the manes of departed beings; inspire men with a love of virtue; and lead them to the practice of their duty." Effects of this supernatural kind are attributed to the sacred music by the inspired writers; as in the case of Saul, out of whom an evil spirit departed at the sound of David's harp; and of Elisha, who was inspired with the spirit of prophecy at the sound of a musical instrument. It is probable therefore, that the relations both of the Greeks and Chinese are founded upon facts of this kind: and we cannot from thence infer, that the music of early ages was at all superior to that which followed. According to those who have employed much time in these researches, the ancient Chinese were acquainted with the division of the octave into twelve semitones; and that before the time of Pythagoras, or even Mercury himself: that the lyre of Pythagoras, his invention of the diatonic tetra-chords, and the formation of his grand system, were merely borrowed from the ancient Chinese. In short, it is maintained, that the Greeks, even Pythagoras himself, did nothing but apply to strings that theory which the Chinese had before formed, and applied to pipes.

At present the Chinese are not acquainted with the use of our musical notes; they have not that diversity of signs which distinguish the different tones, and the gradual elevation or depression of the voice, nor any thing to point out the various modifications of sound to produce harmony. They have only a few characters to mark the principal notes; and all the airs they learn are repeated merely by rote. The emperor Kang-hi was therefore greatly astonished at the facility with which an European could catch and remember an air the first time he heard it. In 1679 he sent for Fathers Grimaldi and Pereira, to play some tunes on the harpsichord, of which they had before made him a present. He was greatly entertained with their music, but altogether astonished when he found that F. Pereira could take down a Chinese air while the musicians were playing it, and then repeat the whole without omitting a single note. Having made several trials of this kind in order to satisfy himself, he bestowed the highest encomiums upon the European music, and the means furnished by it to facilitate and lessen the labour of the memory. "I must confess (says he) that the European music is incomparable, and that the like of this F. Pereira is not to be found in my whole kingdom."

The Chinese have always distinguished eight different sounds; and they believe that nature, in order to produce these, formed eight different kinds of sonorous bodies. The order in which they distribute these sounds, and the instruments they have contrived to produce them, are, 1. The sound of skin produced by drums. 2. That of stone produced by the *king*. 3. The sound of metal by bells. 4. That of baked earth by the *huien*. 5. Of silk by the *kin* and *che*. 6. Of wood

China.

134
Musical in-
struments.

China. wood by the *yu*, and *tchou*. 7. Of the bamboo by the *koan*, and different flutes. 8. That of a gourd by the *cheng*.

The drums were originally composed of a box made of baked earth, and covered at the extremities with the skin of some animal; but on account of the brittleness of baked earth, wood was soon substituted in its stead. Greater part of these instruments are shaped like our barrels, but some are cylindric.

The instruments formed of the sonorous stones are called *king*, distinguished into *tse-king* and *pien-king*. The *tse-king* consists only of one stone, and therefore produces only one note. The *pien-king* consists of 16 stones suspended together, and thus forming an instrument capable of producing all the tones admitted into the music of the ancient Chinese. They are cut into the form of a carpenter's square; their tone is flattened by diminishing their thickness, and is made sharper by abridging their length.

135
Bells of immense size.

The bells in China have always been made of a mixture of tin and copper. They are of different shapes, and those of the ancients were not round, but flatted, and in the lower part resembling a crescent. An instrument, corresponding to the *king* already mentioned, is composed of 16 bells of different sizes. Some of their bells used on public occasions are of enormous magnitudes. One at Peking is described as $13\frac{1}{2}$ feet in diameter, $12\frac{1}{2}$ in height, and 42 in circumference; the weight being upwards of 120,000 pounds. It is used for announcing the hours or watches of the night; and its sound, which is prodigiously loud and strong, has a most awful effect in the night-time, by reverberating round the walls and the echo of the surrounding country. There are several others likewise of vast size in the same city; one of which deserves greatly to be admired on account of the beautiful characters with which it is covered; and which are as neat and perfect as if traced out by the hand of the finest writer, or formed by means of a stamp upon wax. F. le Comte tells us, that in all the cities of China there are bells for marking the hours and watches of the night. They generally divide the night into five watches, beginning at seven or eight in the evening. On the commencement of the first they give one stroke, which is repeated a moment after; and thus they continue for two hours till the beginning of the second: they then give two strokes, which are repeated at equal intervals till the beginning of the third watch; and thus they proceed to the fourth and fifth, always increasing the number of the strokes. For the same purpose also they use enormous drums, which they beat in a similar manner. F. Magaillans mentions one at Peking upwards of 40 feet in circumference.

The instrument called *huien*, which is made of baked earth, is highly esteemed by the Chinese on account of its antiquity. It is distinguished into two kinds, the great and small; the former being of the size of a goose's egg; the latter of that of a hen's. It has six holes for the notes, and a seventh for the mouth.

The *kin* and *tche* have been known from the remotest antiquity. The *kin* has seven strings made of silk, and is distinguished into three kinds, differing only in size. The body is formed of a kind of wood varnished black, and its whole length about five feet

five inches. The *che* is about nine feet in length, has 25 strings, and is divided into 25 kinds. F. Amiot assures us, that we have no instrument in Europe which deserves to be preferred to it.

The instruments which emit the sound of wood are the *tchou*, the *yu*, and the *tchoung-tou*. The first is shaped like a bushel, and is beat on the inside with a hammer; the second, which represents a tyger squatting, is made to sound by scraping its back gently with a rod; the third is a collection of twelve pieces of boards tied together, which are used for beating time, by holding them in the right hand, and knocking them gently against the palm of the left.

Many instruments are constructed of the bamboo. These consist of pipes joined together, or separate, and pierced with more or fewer holes. The principal of all these wind instruments is the *cheng*, which emits the sound of a gourd. This is formed by cutting off the neck of a gourd, and reserving only the lower part. To this a cover is fitted, having as many holes as are equal to the number of sounds required. In each of these holes a pipe made of bamboo is fixed, and shorter or longer according to the tone intended. The mouth of the instrument is formed of another pipe shaped like the neck of a goose; which is fixed to the gourd on one side, and serves to convey the air to all the pipes it contains. The ancient *cheng* varied in the number of their pipes; those used at present have only 13.

The painting of the Chinese is undoubtedly inferior to that of the Europeans, though we are not by any means to judge of the abilities of the painters of this empire by the performances which are brought to Europe. M. Grosier remarks, that the works of the eminent Chinese painters are never brought to Canton, because they cannot find purchasers among the European merchants. The latter delight only in obscene pictures, which are not permitted by government, nor indeed will any artist of character execute them, though they prevail upon some of the inferior daubers to gratify them in this respect. It seems, however, to be universally agreed, that the Chinese have no notion of correctness or perspective, and little knowledge of the proportions of the human body, though it cannot be denied that they excel in painting flowers and animals. In these they pride themselves in a scrupulously exact imitation of nature, inasmuch that it is no uncommon thing to hear a painter ask his pupil how many scales there are between the head and tail of a carp.

136
Chinese painting.

Painting was formerly much esteemed in China, but has now fallen into disrepute on account of its political inutility. The cabinets and galleries of the emperor, however, are filled with European paintings, and the celebrated artists Castiglioni and Attiret were both employed; but their offer of erecting a school of painting was rejected, lest they should by this means revive the taste for that art which it had been formerly thought prudent to suppress.

Painting in fresco was known in China long before the Christian æra; and, like the Grecians, the Chinese boast much of their celebrated painters of antiquity. Thus we are told of a door painted by Fan-hien, which was so perfect an imitation, that the people who entered the temple where it was attempted to go out by it, unless prevented by those who had seen it before.

China.

The present emperor has in his park an European village painted in fresco, which produces the most agreeable deception. The remaining part of the wall represents a landscape and little hills, which are so happily blended with the distant mountains, that nothing can be conceived more agreeable. This was the production of Chinese painters, and executed from designs sketched out for them.

137
Engraving.

Engraving in three, four, or five colours, is very ancient among the Chinese, and was known in this empire long before its discovery in Europe.

138
Sculpture.

Sculpture is very little known in this empire; nor is there a single statue in any of the squares or public edifices of Peking, not even in the emperor's palace. The only real statues to be met with in the empire are those which, for the sake of ceremonious distinction, are used to ornament the avenues leading to the tombs of princes and men of great rank; or those that are placed near the emperor's coffin, and that of his sons and daughters in the interior part of the vault, where their remains are deposited.

139
Architecture.

The Chinese architecture is entirely different from that of the Greeks or Romans; but nevertheless has certain proportions of its own, and a beauty peculiar to itself. The habitations of the emperor are real palaces, and announce in a striking manner the majesty and grandeur of the master who inhabits them. All the missionaries who had access to the inside of the emperor's palace at Peking, agreed, that if each of its parts, taken separately, does not afford so much delight to the eye as some pieces of the grand architecture of Europe, the whole presents a sight superior to any thing they had ever seen before. In the Chinese architecture, when a pillar is two feet diameter at the base, its height must be 14 feet; and by measures of this kind the height of every building is determined.

Almost all the houses and buildings in China are constructed of wood. One reason of this may be the dread of earthquakes; but, besides this, such buildings are rendered eligible by the heat and dampness of the southern provinces, and the excessive cold in the northern, which would render stone houses almost uninhabitable. Even at Peking, where the rains are but of short duration, it is found necessary to cover the small marble stair-cases belonging to the imperial palace with pieces of felt: the humidity of the air moistens and soaks into every thing. During winter the cold is so exceedingly severe, that no window can be opened to the north; and water continues constantly frozen to the depth of a foot and a half for more than three months. For the same reasons a variety of stories are not used in the Chinese buildings; as neither a second nor third story would be habitable during the great heats of summer or the rigorous cold of winter. Though Peking is situated in the northern part of the empire, the heat there, during the dog-days, is so intolerably scorching, that the police obliges tradesmen and shopkeepers to sleep in the open air in the piazzas of their houses, lest they should be stifled by retiring into their inner apartments. The habitations of people of rank, or of those in easy circumstances, generally consist of five large courts, inclosed with buildings on every side. The method of building with several stories was, however, followed for several

centuries, when the court resided in the southern provinces; and the taste for this kind of building was carried to such an height, that immense edifices were erected from 150 to 200 feet in height, and the pavilions or towers at the extremities rose upwards of 300 feet. This kind of building, however, at length became disgusting; though, either to preserve the remembrance of it, or for the sake of variety, there are still some buildings to be seen several stories high in the palaces belonging to the emperor.

China.

A multiplicity of bridges are rendered necessary in China by the vast number of canals and rivers which intersect the empire. Anciently, however, the Chinese bridges were much more ingenious as well as magnificent than they are at present. Some of them were so contrived that they could be erected in one day to supply the place of others which might happen to be broken down, or for other purposes. At that time they had bridges which derived their name from their figure; as *resembling the rainbow*; *draw-bridges*, *bridges to move with pulleys*, *compass-bridge*, &c. with many others entirely unknown at present. The building of bridges indeed was once a luxurious folly of the emperors; so that they were multiplied from whim or caprice, without any necessity, and without use. Still, however, many of them are extremely beautiful and magnificent. The arches of some are very lofty and acute, with easy stairs on each side, the steps of which are not quite three inches in thickness, for the greater facility of ascending and descending: others have no arches, but are composed of large stones, sometimes 18 feet in length, placed transversely upon piles like planks. Some of these bridges are constructed of stone, marble, or brick; others of wood; and some are formed of a certain number of barks joined together by very strong iron chains. These are known by the name of floating bridges, and several of them are to be seen on the large rivers Kiang and Hoang-ho.

140
Bridges.

For several centuries the Chinese have made no progress in ship-building. Their vessels have neither mizen, bowsprit, nor top-mast. They have only a main and fore mast, to which is sometimes added a small top-gallant-mast. The main-mast is placed almost in the same part of the deck as ours; but the fore-mast stands much farther forward. The latter is to the former in the proportion of two to three; and the main-mast is generally two-thirds of the length of the vessel. They use mats for sails, strengthening them with whole bamboos equal in length to the breadth of the sail, and extended across it at the distance of a foot from one another. Two pieces of wood are fixed to the top and bottom of the sail; the upper serves as a sail-yard; and the lower, which is about five or six inches in thickness, keeps the sail stretched when it is necessary to hoist or lower it. This kind of sail may be folded or unfolded like a screen. For caulking their vessels they do not use pitch, but a particular kind of gum mixed with lime, which forms a composition of such excellent quality, that one or two wells in the hold are sufficient to keep the vessel dry. They have not yet adopted the use of pumps, and therefore draw up the water with buckets. Their anchors are made of the hard wood called *iron-wood*, which they say is much superior.

141

Shipbuilding.

China
||
Chio.

superior to the metal, because the latter sometimes bend, but the former never do.

The Chinese pretend to have been the first inventors of the mariner's compass, but seem to have little inclination to improve such an important machine: however, they are well acquainted with the art of manœuvring a vessel, and make excellent coasting pilots, though they are bad sailors in an open sea.

CHINA-Root, in the materia medica, the root of a species of *SMILAX*, brought both from the East and West Indies; and thence distinguished into oriental and occidental. Both sorts are longish, full of joints, of a pale-reddish colour, with no smell, and very little taste. The oriental, which is the most esteemed, is considerably harder and paler-coloured than the other. Such should be chosen as is fresh, close, heavy, and upon being chewed appears full of a fat unctuous juice. It is generally supposed to promote insensible perspiration and the urinary discharge, and by its unctuous quality to obtund acrimonious juices. China-root was first brought into Europe in the year 1535, and used as a specific against venereal and cutaneous disorders. With this view it was made use of for some time; but has long since given place to more powerful medicines.

CHINA-Ware. See PORCELAIN.

CHINCA, a sea-port town of Peru in South America, situated in an extensive valley of the same name, in W. Long. 76. O. S. Lat. 13. O.

CHINCOUGH, a convulsive kind of cough to which children are generally subject. See *MEDICINE-Index*.

CHINESE, in general denotes any thing belonging to China, or its inhabitants.

CHINESE Swanpan. See SWANPAN.

CHINKAPIN. See FAGUS.

CHINNOR, a musical instrument among the Hebrews, consisting of 32 chords. Kircher has given a figure of it, which is copied on Plate CXXXV.

CHINON, an ancient town of Tourain in France, remarkable for the death of Henry II. king of England, and for the birth of the famous Rabelais. It is seated on the river Vienne, in a fertile and pleasant country, in E. Long. O. 18. N. Lat. 47. 2.

CHIO, or *CHIOS*, an Asiatic island lying near the coast of Natolia, opposite to the peninsula of Ionia. It was known to the ancients by the name of *Æthalia*, *Macris*, *Pithynsa*, &c. as well as that of *Chios*. According to Herodotus, the island of Chios was peopled originally from Ionia. It was at first governed by kings; but afterwards the government assumed a republican form, which by the direction of Isocrates was modelled after that of Athens. They were, however, soon enslaved by tyrants, and afterwards conquered by Cyrus king of Persia. They joined the other Grecians in the Ionian revolt; but were shamefully abandoned by the Samians, Lesbians, and others of their allies; so that they were again reduced under the yoke of the Persians, who treated them with the utmost severity. They continued subject to them till the battle of Mycale, when they were restored to their ancient liberty: this they enjoyed till the downfall of the Persian empire, when they became subject to the Macedonian princes. In the time of the emperor Vespasian the island was reduced to the

form of a Roman province; but the inhabitants were allowed to live according to their own laws under the superintendence of a prætor. It is now subject to the Turks, and is called *Scio*. See that article.

CHIOCOCCA, in botany: A genus of the monogynia order, belonging to the pentandria class of plants; and in the natural method ranking under the 48th order, *Aggregate*. The corolla is funnel-shaped and equal; the berry unilocular, dispermous, inferior.

CHIONANTHUS, the SNOW-DROP or FRINGE TREE: A genus of the monogynia order, belonging to the diandria class of plants; and in the natural method ranking under the 44th order, *Sepiaria*. The corolla is quadrifid, with the segments very long; the fruit is a plum. There is but one species particularly described by botanists, viz. the *Virginica*. It is common in Virginia and South Carolina, where it grows by the sides of rivulets. It rises to the height of ten feet; the leaves are as large as those of the laurel, but much thinner. The flowers come out in May, and are of a pure white; from whence it has the name of the *snow-drop tree*. They hang down in large branches, and are cut into narrow segments; from which it has got its other name of the *fringe-tree*. After the flowers are fallen off, the fruit appears, which grows to the size of a sloe, having a stone in the middle. The plants are propagated from seeds sown on a hot-bed, and kept in a stove. Some have been raised from layers; but this method is very precarious, and therefore the other is to be preferred. The seeds must be procured from America, for they never come to perfection in this country.

CHIONE, in fabulous history, was daughter of Dædalion, of whom Apollo and Mercury became enamoured. To enjoy her company, Mercury lulled her to sleep with his caduceus; and Apollo, in the night, under the form of an old woman, obtained the same favours as Mercury. From this embrace Chione became mother of Philammon and Autolycus; the former of whom, as being son of Apollo, became an excellent musician; and the latter was equally notorious for his robberies, of which his father Mercury was the patron. Chione grew so proud of her commerce with the gods, that she even preferred her beauty to that of Juno; for which impiety she was killed by the goddesses and changed into a hawk.—Another of the same name was daughter of Boreas and Orithyia, who had Eumolpus by Neptune. She threw her son into the sea; but he was preserved by his father.

CHIOS. See *CHIO* and *SCIO*.

CHIOURLIC, an ancient town of Turkey in Europe, and in Romania, with a see of a Greek bishop. It is seated on a river of the same name, in E. Long. 7. 47. N. Lat. 41. 18.

CHIOZZO, an ancient and handsome town of Italy, in the territory of Venice, and in a small island, near the Lagunes, with a podesta, a bishop's see, and a harbour defended by a fort. E. Long. 12. 23. N. Lat. 45. 17.

CHIPPENHAM, a town of Wiltshire, seated on the river Avon. It is a good thoroughfare town; has a handsome stone-bridge over the river, consisting of 16 arches; and sends two members to parliament.

Chipping. There is here a manufacture of the best superfine wool-len cloth in England. W. Long. 2. 12. N. Lat. 51. 25.

CHIPPING, a phrase used by the potters and china-men to express that common accident both of our own stone and earthen ware, and the porcelain of China, the flying off of small pieces, or breaking at the edges. Our earthen wares are particularly subject to this, and are always spoiled by it before any other flaw appears in them. Our stone-wares escape it better than these; but not so well as the porcelain of China, which is less subject to it than any other manufacture in the world. The method by which the Chinese defend their ware from this accident, is this: They carefully burn some small bamboo canes to a sort of charcoal, which is very light, and very black; this they reduce to a fine powder, and then mix it into a thin paste, with some of the varnish which they use for their ware: they next take the vessels when dried, and not yet baked, to the wheel; and turning them softly round, they, with a pencil dipt in this paste, cover the whole circumference with a thin coat of it: after this, the vessel is again dried; and the border made with this paste appears of a pale greyish colour when it is thoroughly dry. They work on it afterwards in the common way, covering both this edge and the rest of the vessel with the common varnish. When the whole is baked on, the colour given by the ashes disappears, and the edges are as white as any other part; only when the baking has not been sufficient, or the edges have not been covered with the second varnishing, we sometimes find a dusky edge, as in some of the ordinary thick tea-cups. It may be a great advantage to our English manufactures to attempt something of this kind. The willow is known to make a very light and black charcoal; but the elder, though a thing seldom used, greatly exceeds it. The young green shoots of this shrub, which are almost all pith, make the lightest and the blackest of all charcoal; this readily mixes with any liquid, and might be easily used in the same way that the Chinese use the charcoal of the bamboo cane, which is a light hollow vegetable, more resembling the elder shoots than any other English plant. It is no wonder that the fixed salt and oil contained in this charcoal should be able to penetrate the yet raw edges of the ware, and to give them in the subsequent baking a somewhat different degree of vitrification from the other parts of the vessel; which, though, if given to the whole, it might take off from the true semivitrified state of that ware, yet at the edges is not to be regarded, and only serves to defend them from common accidents, and keep them entire. The Chinese use two cautions in this application: the first in the preparation; the second in the laying it on. They prepare the bamboo canes for burning into charcoal, by peeling off the rind. This might easily be done with our elder shoots, which are so succulent, that the bark strips off with a touch. The Chinese say, that if this is not done with their bamboo, the edges touched with the paste will burst in the baking: this does not seem indeed very probable; but the charcoal will certainly be lighter made from the peeled sticks, and this is a known advantage. The other caution is, never to touch the vessel with hands that have any greasy or fatty sub-

stance about them; for if this is done, they always find the vessel crack in that place.

CHIROGRAPH, was anciently a deed which, requiring a counterpart, was engrossed twice on the same piece of parchment, counterwise; leaving a space between, wherein was written **CHIROGRAPH**; through the middle whereof the parchment was cut, sometimes straight, sometimes indentedly; and a moiety given to each of the parties. This was afterwards called *dividenda*, and *charta divisa*; and was the same with what we now call *charter-party*. See **CHARTER-Party**. The first use of these chirographs, with us, was in the time of Henry III.

CHIROGRAPH was also anciently used for a fine: and the manner of engrossing the fines, and cutting the parchment in two pieces, is still retained in the office called the *chirographer's office*.

CHIROGRAPHER of FINES, an officer in the common pleas, who engrosses **FINES** acknowledged in that court into a perpetual record (after they have been examined, and passed by other officers), and writes and delivers the indentures thereof to the party. He makes two indentures; one for the buyer, the other for the seller; and a third indented piece, containing the effect of the fine, and called *the foot of the fine*; and delivers it to the *custos brevium*.—The same officer also, or his deputy, proclaims all fines in court every term, and indorses the proclamations on the backside of the foot; keeping, withal, the writ of covenant, and the note of the fine.

CHIROMANCY, a species of divination drawn from the lines and lineaments of a person's hand; by which means, it is pretended, the dispositions may be discovered. See **DIVINATION**, n^o 9.

CHIRON, a famous personage of antiquity; styled by Plutarch, in his dialogue on music, "*The wise Centaur*." Sir Isaac Newton places his birth in the first age after Deucalion's deluge, commonly called the *Golden Age*; and adds, that he formed the constellations for the use of the Argonauts, when he was 88 years old; for he was a practical astronomer, as well as his daughter Hippo: he may, therefore, be said to have flourished in the earliest ages of Greece, as he preceded the conquest of the Golden Fleece, and the Trojan war. He is generally called the son of Saturn and Philyra; and is said to have been born in Thesfaly among the **CENTAURS**, who were the first Greeks that had acquired the art of breaking and riding horses: whence the poets, painters, and sculptors, have represented them as a compound of man and horse; and perhaps it was at first imagined by the Greeks, as well as the Americans, when they first saw cavalry, that the horse and the rider constituted the same animal.

Chiron was represented by the ancients as one of the first inventors of medicine, botany, and *chirurgery*; a word which some etymologists have derived from his name. He inhabited a grotto or cave in the foot of Mount Pelion, which, from his wisdom and great knowledge of all kinds, became the most famous and frequented school throughout Greece. Almost all the heroes of his time were fond of receiving his instructions; and Xenophon, who enumerates them, names the following illustrious personages among his disciples: Cephalus, Æsculapius, Melanion, Nestor, Amphiaræus,

Chiron,
Chironia.

phiarus, Peleus, Telamon, Meleager, Theseus, Hippolitus, Palamedes, Ulysses, Mnestheus, Diomedes, Castor and Pollux, Machaon and Podalirius, Antilochus, Æneas, and Achilles. From this catalogue it appears, that Chiron frequently instructed both fathers and sons; and Xenophon has given a short eulogium on each, which may be read in his works, and which redounds to the honour of the preceptor. The Greek historian, however, has omitted naming several of his scholars, such as Bacchus, Phoenix, Cocytus, Arystæus, Jason, and his son Medeus, Ajax, and Protefilaus. Of these we shall only take notice of such as interest Chiron more particularly. It is pretended that the Grecian Bacchus was the favourite scholar of the Centaur; and that he learned of this master the revels, orgies, bacchanalia, and other ceremonies of his worship. According to Plutarch, it was likewise at the school of Chiron that Hercules studied music, medicine, and justice; though Diodorus Siculus tells us, that Linus was the music-master of this hero. But among all the heroes who have been disciples of this Centaur, no one reflected so much honour upon him as Achilles, whose renown he in some measure shared; and to whose education he in a particular manner attended, being his grandfather by the mother's side. Apollodorus tells us, that the study of music employed a considerable part of the time which he bestowed upon his young pupil, as an incitement to virtuous actions, and a bridle to the impetuosity of his temper. One of the best remains of antique painting now existing, is a picture upon this subject, dug out of the ruins of Herculaneum, in which Chiron is teaching the young Achilles to play on the lyre. The death of this philosophic musician was occasioned, at an extreme old age, by an accidental wound in the knee with a poisoned arrow, shot by his scholar Hercules at another. He was placed after his death by Musæus among the constellations, through respect for his virtues, and in gratitude for the great services which he had rendered the people of Greece. Sir Isaac Newton says*, in proof of the constellations being formed by Chiron and Musæus for the use and honour of the Argonauts, that nothing later than the expedition was delineated on the sphere; according to the same author, Chiron lived till after the Argonautic expedition, in which he had two grandsons. The ancients have not failed to attribute to him several writings; among which, according to Suidas, are *precepts*, *υποθηκας*, in verse, composed for the use of Achilles; and a medicinal treatise on the *diseases incident to horses* and other quadrupeds, *ἰππιατρικον*; the lexicographer even pretends, that it is from this work the Centaur derived his name. Fabricius gives a list of the works attributed to Chiron, and discusses the claims which have been made for others to the same writings; and in vol. xiii. he gives him a distinguished place in his catalogue of ancient physicians.

CHIRONIA, in botany: A genus of the monogynia order, belonging to the pentandria class of plants; and in the natural method ranking under the 20th order, *Rotaceæ*. The corolla is wheel-shaped; the pistil declining downwards; the stamina placed in the tube of the corolla; the antheræ in their last stage spiral; the seed-case bilocular. There are eight

species, of which the *frutescens* is the most remarkable. It is a native of the Cape of Good Hope. The root is fibrous, and spreads near the surface of the ground. The stalks are round, and inclining to be ligneous, but are of a very soft texture; these rise from two to three feet high, sending out several branches which grow erect, and are garnished with succulent leaves an inch or more in length, and about an eighth of an inch in breadth. At the end of each shoot the flowers are produced, which are tubulous, and spread open at the top; they are of a bright red colour; and when there are a large number of flowers open on the same plant, they make a fine appearance. The flowers are produced from June to autumn; and the seeds ripen in October. The plants are propagated by seeds, which must be sown in pots filled with light sandy earth, and plunged in a moderate hot-bed. In summer they may be injured to the open air; but must always be sheltered in winter.

CHIRONOMY, in antiquity, the art of representing any past transaction by the gestures of the body, more especially by the motions of the hands: this made a part of liberal education; it had the approbation of Socrates, and was ranked by Plato among the political virtues.

CHIROTONY, among ecclesiastical writers, denotes the imposition of hands used in conferring priestly orders. However, it is proper to remark, that chirotony originally was a method of electing magistrates, by holding up the hands.

CHIRURGEON, or **SURGEON**. See **SURGEON**.

CHIRURGERY. See **SURGERY**.

CHISLEY-LAND, in agriculture, a soil of a middle nature between sandy and clayey land, with a large admixture of pebbles.

CHISON, **KISON**, or **KISSON**, (Judges iv. and v.), a river of Galilee; said to rise in mount Tabor, to run by the town of Naim, and to fall into the Mediterranean between mount Carmel and Ptolemais, 1 Kings xviii. 40.

CHISSEL, or **CHISEL**, an instrument much used in sculpture, masonry, joinery, carpentry, &c.

There are chisels of different kinds; though their chief difference lies in their different size and strength, as being all made of steel well sharpened and tempered: but they have different names, according to the different uses to which they are applied.—The chisels used in carpentry and joinery are, 1. The former; which is used first of all before the paring-chisel, and just after the work is scribed. 2. The paring-chisel; which has a fine smooth edge, and is used to pare off or smooth the irregularities which the former makes. This is not struck with a mallet as the former is, but is pressed with the shoulder of the workman. 3. Skew-former: this is used for cleansing acute angles with the point or corner of its narrow edge. 4. The mortise-chisel; which is narrow, but very thick and strong, to endure hard blows, and it is cut to a very broad basil. Its use is to cut deep square holes in the wood for mortises. 5. The gouge, which is a chisel with a round edge; one side whereof serves to prepare the way for an augre, and the other to cut such wood as is to be rounded, hollowed, &c. 6. Socket-chisels, which are chiefly used by carpenters, &c. have their

Chironomy

Chissel.

Chiton || **Chivalry.** Shank made with a hollow socket at top, to receive a strong wooden sprig, fitted into it with a shoulder. These chissels are distinguished, according to the breadth of the blade, into half-inch chissels, three quarters of an inch chissels, &c. 7. Ripping-chissels; which is a socket-chissel of an inch broad, having a blunt edge, with no basil to it. Its use is to rip or tear two pieces of wood asunder, by forcing in the blunt edge between them.

- **CHITON**, in zoology, a genus of the order of vermes testaceæ. The name *chiton* is from *χιτών*, *Loricæ*, a coat of mail. The shell is plated, and consists of many parts lying upon each other transversely: the inhabitant is a species of the **DORIS**. They are common on the shores of Scarborough, Aberdeen, and Lochbroom. See several species represented of their natural size on Plate CXXXVIII.

CHITTIM (anc. geog.), according to Le Clerc, Calmet, and others, was the same with Macedonia, peopled by Kittim the son of Javan and grandson of Noah.

CHITTRICK'S MEDICINE FOR THE STONE. This medicine was some years ago kept as a secret, and had great reputation as a lithontriptic, which indeed it seems in many cases to deserve. It was discovered by Dr Blackrie to be no other than soap-lye; and the following receipt for using it was procured by General Dunbar: "Take one tea-spoonful of the strongest soap-lye, mixed in two table-spoonfuls of sweet milk, an hour before breakfast and at going to bed. Before you take the medicine, take a sup of pure milk, and immediately after you have swallowed the medicine take another. If you find this agrees with you for two or three days, you may add half as much more to the dose."

¹ Definition.

CHIVALRY; (from *cheval*, "a horse"); an abstract term, used to express the peculiar privileges, obligations, and turn of mind, with all the other distinguishing characteristics of that order of men who flourished in Europe in the dark ages, during the vigour of the feudal systems of government, under the name of *Knights*, or *Knights Errant*.

² Difficulty of tracing the origin of chivalry.

To ascertain the period at which the order sprung up, and the circumstances to which its origin was owing, is no easy task. In the history of society, such a multiplicity of collateral facts appear interwoven together, and causes and effects run into each other by a gradation so imperceptible; that it is exceedingly difficult, even for the nicest eye, to discern causes from their immediate effects, or to distinguish to which among a number of collateral circumstances the origin of any particular event is to be referred. The age to which we must look for the origin of chivalry was singularly rude and illiterate. Even the principal events of that period, emigrations, wars, and the establishment of systems of laws and forms of government, have been but imperfectly, and in many instances unfaithfully, recorded. But the transactions which took place in the ordinary course of civil and domestic life, and which, though less striking, must have always prepared the way for the more remarkable events, have been generally thought unworthy of transmission to posterity, and have very seldom found an historian. Add to these difficulties which oppose our researches on this subject, that the nations of Europe were in

that age a mixed multitude, consisting of the aboriginal inhabitants, who, though either subdued by the Roman arms, or at least compelled to retire to the woods and mountains, still obstinately retained their primitive manners and customs; Roman colonies, and such of the original inhabitants of the countries in which these were established, as had yielded not only to the arms of the Romans, but also to the influence of their laws, arts, and manners; and the barbarians, who proceeding from the northern regions of Asia and Europe, the wilds of Scythia and Germany, dissolved the fabric of the Roman empire, and made themselves lords of Europe. Amid this confusion of nations, institutions, and customs, it becomes almost impossible to trace any regular series of causes and effects.

Yet as the history of that period is not entirely unknown to us, and the obscure and imperfect records in which it is preserved, while they commemorate the more remarkable events, throw a faint light on the customs, manners, and ordinary transactions of the age; we can at least collect some circumstances, which, if they did not of themselves give rise to the institution of chivalry, must certainly have co-operated with others to that end. We may even be allowed, if we proceed with due diffidence and caution, to deduce, from a consideration of the effect, some inferences concerning the cause; from those particulars of its history which are known to us, we may venture to carry imagination backwards, under a proper restraint, to those which are hid under the darkness of a rude and illiterate age.

Distinction of ranks appears to be essentially necessary to the existence of civil order. Even in the simplest and rudest social establishments, we find not merely the natural distinctions of weak and strong, young and old, parent and child, husband and wife; these are always accompanied with others which owe their institution to the invention of man, and the consent, either tacit or formal, of the society among whom they prevail. In peace and in war, such distinctions are equally necessary: they constitute an essential and important part of the mechanism of society.

One of the earliest artificial distinctions introduced among mankind, is that which separates the bold and skilful warrior from those whose feebleness of body and mind renders them unable to excel in dexterity, stratagem, or valour. Among rude nations, who are but imperfectly acquainted with the advantages of social order, this distinction is more remarkably eminent than in any other state of society. The ferocity of the human character in such a period produces almost continual hostilities among neighbouring tribes: the elements of nature, and the brute inhabitants of the forest, are not yet reduced to be subservient to the will of man; and these, with other concomitant circumstances, render the warrior, who is equally distinguished by cunning and valour, more useful and respectable than any other character.

On the same principles, as the boundaries of society are enlarged, and its form becomes more complex, the classes into which it is already distinguished are again subdivided. The invention of arts, and the acquisition of property, are the chief causes of these new distinctions which now arise among the orders of society; and

Chivalry.

³ Distinction of ranks an essential part of the mechanism of society.

⁴ The early pre-eminence of the military character.

⁴ Subordinate distinctions of rank introduced into society.

Chivalry. and they extend their influence equally through the whole system. Difference of armour, and different modes of military discipline, produce distinction of orders among those who practise the arts of war; while other circumstances, originating from the same general causes, occasion similar changes to take place amid the scenes of peace.

6
The distinction introduced into the military order by the use of cavalry.

None of the new distinctions which are introduced among men, with respect to the discipline and conduct of war, in consequence of the acquisition of property and the invention of arts, is more remarkable than that occasioned by the use of horses in military expeditions, and the training of them to the evolutions of the military art. Fire-arms, it is true, give to those who are acquainted with them a greater superiority over those to whom their use is unknown than what the horseman possesses over him who fights on foot. But the use of fire-arms is of such importance in war, and the expence attending it so inconsiderable, that wherever these have been introduced, they have seldom been confined to one particular order in an army; and therefore they produce indeed a remarkable, though transient, distinction among different nations; but establish no permanent distinctions in the armies of any one nation. But to maintain a horse, to equip him with costly furniture, to manage him with dexterity and vigour, are circumstances which have invariably produced a standing and conspicuous distinction among the military order, wherever bodies of cavalry have been formed. The Roman *equites*, who, though they became at length a body of usurers and farmers-general, were originally the only body of cavalry employed by the state, occupied a respectable rank between the senators and the plebeians; and the elegance and humanity of their manners were suitable to their rank. In ancient Greece, and in the celebrated monarchies of Asia, the same distinction prevailed at a similar period.

7
Military distinctions among the ancient Germans.

Since the circumstances and principles on which this distinction depends are not such as must be confined in their influence to one particular nation, or one region of the globe, we may hope to trace their effects among the savage warriors of Scythia and Germany, as well as among the Greeks or Romans. From the valuable treatise of Tacitus *de moribus Germanorum*, we learn, that among the German warriors a distinction somewhat of this nature *did* actually subsist; not so much indeed a distinction between the warrior who fought on horseback and those who fought on foot, as between those whom vigour of body and energy of mind enabled to brave all the dangers of war, and such as, from the imbecility of youth, the infirmities of age, or the natural inferiority of their mental and bodily powers, were unequal to scenes of hardship and deeds of valour. The youth was not permitted to take arms and join his warlike countrymen in their military expeditions whenever he himself thought proper. There was a certain age before which he could not be invested with armour. When he had attained that period, if not found deficient in strength, activity, or courage, he was formally honoured with the shield and the lance, called to the duties, and admitted to all the privileges, of a warrior.

Another fact worthy of notice respecting the manners of the barbarians of Germany before they established themselves in the cultivated provinces of the Roman empire is, that their women, contrary to what we find among many other rude nations, were treated with an high degree of respect. They did not generally vie with the men in deeds of valour, but they animated them by their exhortations to distinguish themselves in the field; and virgins especially were considered with a sacred veneration, as endowed with prophetic powers, capable to foresee events hid in the womb of futurity, and even to influence the will of the deities. Hence, though domestic duties were their peculiar province, yet they were not harshly treated nor confined to a state of slavery. There appears indeed a striking analogy between the condition of the women among the rude soldiers of Sparta and the rank which they occupied among the warlike cantons of Germany. Perhaps, indeed, the German were still more honourable than the Spartan women; as they were taught to wield the magic weapons of superstition, which in Greece were appropriated to the priests.

It appears, therefore, that, in the forests of Germany at least, if not in the more northern regions of Asia and Europe, the conquerors of the Roman empire, before they penetrated into its provinces, treated their women with a degree of respect unknown to most of the nations of antiquity; that the character of the warrior was likewise highly honourable, being understood to unite all those qualities which were in the highest estimation; and that it was only at a particular age, and with certain forms, that the youth were admitted to bear arms.

When those nations sallied from their deserts and forests, over-ran the Roman empire, and established themselves in its provinces, the change which took place on their circumstances was remarkable; and by a natural influence, it could not but produce an equally remarkable change on their habits, customs, and manners. The great outlines might still remain; but they could not now fail to be filled up in a different manner. Here, however, the records of history are peculiarly imperfect. We have no Cæsar or Tacitus to supply facts or direct our reasonings; the Gothic nations had not yet learned to read and write; and the Romans were so depressed under the sense of their own miseries, as to be negligent of the changes which happened around them. But as soon as the light of history begins again to dawn, we find that the leading features of the barbarian character were not effaced, but only modified in a particular manner, in consequence of their mixing among a more polished people, becoming acquainted with the luxuries of life, and acquiring extensive power and property.

Those who fought on horseback now began to be distinguished with peculiar honours. The manners of the warrior too were become more cultivated, and his spirit more humane. Leisure and opulence, with the influence of a polished people, even though in a state of slavery, taught those barbarians to aspire after more refined pleasures and more splendid amusements than those which they had been before satisfied with. The influence of Christianity too, which, though grossly corrupted, was still favourable to the social happiness of mankind, concurred to polish their manners and exalt their character. Hence, in the end of the tenth and in the beginning of the eleventh century, we see

Chivalry.
8
Respectability of the women among the Germans.

9
Changes in the manners of the barbarians after they settled in the Roman empire, which gave rise to chivalry.

4 T knight-

Chivalry. knight-errantry, with that romantic gallantry, piety, and humanity, by which it was principally distinguished, make its appearance. At the court of every prince, count, or baron, jousts and tournaments became the favourite amusements. At those entertainments, skill in arms, devotion to the fair, and generous courtesy, were all at once cultivated. About this period began the crusades; and these, to which alone some have referred the origin of chivalry, though they could not give rise to what was already in existence, yet moulded the form and directed the spirit of the institution in such a manner, as to raise it by a rapid progress from infancy, as it were, to full vigour and maturity. Its character, as it appeared when fully formed, is well described by an eloquent historian in the following manner:

Gibbon, vol. vi. p. 26. "Between the age of Charlemagne and that of the crusades, a revolution had taken place among the Spaniards, the Normans, and the French, which was gradually extended to the rest of Europe. The service of the infantry was degraded to the plebeians; the cavalry formed the strength of the armies, and the honourable name of *miles*, or soldier, was confined to the gentlemen who served on horseback, and were invested with the character of knighthood. The dukes and counts, who had usurped the rights of sovereignty, divided the provinces among their faithful barons: the barons distributed among their vassals the fiefs or benefices of their jurisdiction; and these military tenants, the peers of each other and of their lord, composed the noble or equestrian order, which disdained to conceive the peasant or burgher as of the same species with themselves. The dignity of their birth was preserved by pure and equal alliances; their sons alone who could produce four quarters or lines of ancestry, without spot or reproach, might legally pretend to the honour of knighthood; but a valiant plebeian was sometimes enriched and ennobled by the sword, and became the father of a new race. A single knight could impart, according to his judgment, the character which he received; and the warlike sovereigns of Europe derived more glory from this personal distinction than from the lustre of their diadem. This ceremony was in its origin simple and profane; the candidate, after some previous trial, was invested with his sword and spurs; and his cheek or shoulder were touched with a slight blow, as an emblem of the last affront which it was lawful for him to endure. But superstition mingled in every public and private action of life: In the holy wars, it sanctified the profession of arms; and the order of chivalry was assimilated in its rights and privileges to the sacred orders of priesthood. The bath and white garment of the novice, were an indecent copy of the regeneration of baptism: his sword, which he offered on the altar, was blessed by the ministers of religion; his solemn reception was preceded by fasts and vigils; and he was created a knight in the name of God, of St George, and of St Michael the archangel. He swore to accomplish the duties of his profession; and education, example, and the public opinion, were the inviolable guardians of his oath. As the champion of God and the ladies, he devoted himself to speak the truth; to maintain the right; to protect the distressed; to practise *courtesy*, a virtue less familiar to the ancients; to pursue

the infidels; to despise the allurements of ease and safety; and to vindicate in every perilous adventure the honour of his character. The abuse of the same spirit provoked the illiterate knight to disdain the arts of industry and peace; to esteem himself the sole judge and avenger of his own injuries; and proudly to neglect the laws of civil society and military discipline. Yet the benefits of this institution, to refine the temper of Barbarians, and to infuse some principles, of faith, justice, and humanity, were strongly felt, and have been often observed. The asperity of national prejudice was softened; and the community of religion and arms spread a similar colour and generous emulation over the face of Christendom. Abroad, in enterprise and pilgrimage; at home, in martial exercise, the warriors of every country were perpetually associated; and impartial taste must prefer a Gothic tournament to the Olympic games of classic antiquity. Instead of the naked spectacles which corrupted the manners of the Greeks, and banished from the stadium the virgins and matrons, the pompous decoration of the lists was crowned with the presence of chaste and high-born beauty, from whose hands the conqueror received the prize of his dexterity and courage. The skill and strength that were exerted in wrestling and boxing, bear a distant and doubtful relation to the merit of a soldier; but the tournaments, as they were invented in France, and eagerly adopted both in the east and west, presented a lively image of the business of the field. The single combats, the general skirmish, the defence of a pass or castle, were rehearsed as in actual service; and the contest, both in real and mimic war, was decided by the superior management of the horse and lance. The lance was the proper and peculiar weapon of the knight: his horse was of a large and heavy breed; but this charger, till he was roused by the approaching danger, was usually led by an attendant, and he quietly rode a pad or palfrey of a more easy pace. His helmet and sword, his greaves and buckler, it would be superfluous to describe; but I may remark, that at the period of the crusades, the armour was less ponderous than in later times; and that, instead of a massy cuirass, his breast was defended by an hauberk or coat of mail. When their long lances were fixed in the rest, the warriors furiously spurred their horses against the foe; and the light cavalry of the Turks and Arabs could seldom stand against the direct and impetuous weight of their charge. Each knight was attended to the field by his faithful squire, a youth of equal birth and similar hopes; he was followed by his archers and men at arms; and four, or five, or six soldiers, were computed as the furniture of a complete *lance*. In the expeditions to the neighbouring kingdoms or the Holy Land, the duties of the feudal tenure no longer subsisted; the voluntary service of the knights and their followers was either prompted by zeal or attachment, or purchased with rewards and promises; and the numbers of each squadron were measured by the power, the wealth, and the fame of each independent chieftain. They were distinguished by his banner, his armorial coat, and his cry of war; and the most ancient families of Europe must seek in these achievements the origin and proof of their nobility."

The respectable author of the Letters on Chivalry and

Chivalry and Romance, traces, with great ingenuity and erudition, a strong resemblance between the manners of the age of chivalry and those of the old heroic ages delineated by Homer.

10
The resemblance between heroic and Gothic manners.

There is, says she, a remarkable correspondence between the manners of the old heroic times, as painted by their great romancer Homer, and those which are represented to us in the modern books of knight-errantry. A fact of which no good account can be given, but by another not less certain; that the political states of Greece, in the earliest periods of its story, was similar in many respects to that of Europe, as broken by the feudal system into an infinite number of petty independent governments.

Some obvious circumstances of agreement between the heroic and Gothic manners may be worth putting down.

1. The military enthusiasm of the barons is but of a piece with the fanaticism of the heroes. Hence the same particularity of description in the accounts of battles, wounds, deaths, in the Greek poet as in the Gothic romancers. Hence that minute curiosity in the display of their dresses, arms, accoutrements. The minds of all men being occupied with warlike images and ideas, were much gratified by those details, which appear cold and uninteresting to modern readers.

We hear much of knights-errant encountering giants and quelling savages in books of chivalry. These giants were oppressive feudal lords; and every lord was to be met with, like the giant, in his strong-hold or castle. Their dependents of a lower form, who imitated the violence of their superiors, and had not their castles but lurking places, were the savages of romance. The greater lord was called a giant for his power; the less, a savage for his brutality.

2. Another terror of the Gothic ages was monsters, dragons, and serpents. Their stories were received in those days for several reasons: 1. From the vulgar belief of enchantments: 2. From their being reported on the faith of eastern tradition, by adventurers from the holy land: 3. In still later times from the strange things told and believed on the discovery of the new world.

In all these respects, Greek antiquity resembles the Gothic. For what are Homer's Læstrigons and Cyclops, but bands of lawless savages, with each of them a giant of enormous size at their head? And what are the Grecian Bacchus, Hercules, and Theseus, but knights-errant, the exact counterparts of Sir Launcelot and Amadis de Gaul?

3. The oppressions which it was the glory of the knights to avenge, were frequently carried on, as we are told, by the *charms and enchantments of women*. These charms, we may suppose, are often metaphorical; as expressing only the blandishments of the sex. Sometimes they are taken to be real, the ignorance of those ages acquiescing in such conceits. And are not these stories matched by those of Calypso and Circe, the enchantresses of the Greek poet?

4. Robbery and Piracy were honourable in both: so far were they from reflecting any discredit on the ancient or modern *redressers of wrongs*. What account can be given of this, but that, in the feudal times, and in the early days of Greece, when government was weak, and unable to redress the injuries of petty sovereigns, it would be glorious for private ad-

Chivalry. venturers to undertake this work; and, if they could accomplish it in no other way, to pay them in kind by downright plunder and rapine?

5. Bastardy was in credit with both. They were extremely watchful over the chastity of their own women; but such as they could seize upon in the enemies' quarter, were lawful prize. Or if, at any time, they transgressed in this sort at home, the fault was covered by an ingenious fiction. The offspring was reputed divine. Their greatest heroes were the fruit of goddesses approached by mortals; just as we hear of the doughtiest knights being born of fairies.

6. With the greatest fierceness and savageness of character, the utmost generosity, hospitality, and courtesy, were imputed to the heroic ages. Achilles was at once the most relentless, vindictive, implacable, and the friendliest of men. We have the very same representation in the Gothic romances. As in those lawless times, dangers and distresses of all kinds abounded, there would be the same demand for compassion, gentleness, and generous attachments to the unfortunate, those especially of their own clan, as of resentment, rage, and animosity against their enemies.

7. Again, the martial games celebrated in ancient Greece, on great and solemn occasions, had the same origin and the same purpose as the tournaments of the Gothic warriors.

8. Lastly, the passions for adventures so natural in their situation, would be as naturally attended with the love of praise and glory. Hence the same encouragement, in the old Greek and Gothic times, to pænegrists and poets. In the affairs of religion and gallantry, indeed, the resemblance between the hero and the knight is not so striking. But the religious character of the knight was an accident of the times, and no proper effect of his civil condition. And that his devotion for the fair sex should so far surpass that of the hero, is a confirmation of the system here advanced. For the consideration had of the females in the feudal constitution, will of itself account for this deference. It made them capable of succeeding to fiefs, as well as the men. And does not one see, on the instant, what respect and dependence this privilege would draw upon them?

It was of mighty consequence who should obtain the favour of a rich heiress. And though, in the strict feudal times, she was supposed to be in the power and at the disposal of her superior lord, yet this rigid state of things did not last long. Hence we find some distressed damsel was the spring and mover of every knight's adventure. She was to be rescued by his arms, or won by the fame and admiration of his prowess. The plain meaning of all which was this: That as, in these turbulent times, a protector was necessary to the weakness of the sex, so the courteous and valorous knight was to approve himself fully qualified for that purpose.

It may be observed, that the two poems of Homer were intended to expose the mischiefs and inconveniences arising from the political state of Old Greece: the *Iliad*, the dissensions that naturally spring up among independent chiefs; and the *Odyssey*, the insolence of their greater subjects, more especially when unrestrained by the presence of their sovereign. And can any thing more exactly resemble the condition of

Chivalry. the feudal times, when, on occasion of any great enterprise, as that of the crusades, the designs of the confederate Christian states were perpetually frustrated, or interrupted at least, by the dissensions of their leaders; and their affairs at home, as perpetually distressed and disordered by the rebellious usurpations of their greater vassals? Jerusalem was to the European what Troy had been to the Grecian princes. See the article KNIGHT.

CHIVALRY, in law, is used for a tenure of lands by knight's service; whereby the knight was bound to perform service in war unto the king, or the mesne lord of whom he held by that tenure. And chivalry was either general or special: *general*, when it was only in the feoffment that the tenant held *per servitium militare*, without any specification of sergeantry, *escuage*, &c.; *special*, when it was declared particularly by what kind of knight service the land was held.

For the better understanding of this tenure it hath been observed, that there is no law but is holden mediately or immediately of the crown by some service; and therefore all freeholds that are to us and our heirs, are called *feuda*, or *feoda*, "fees;" as proceeding from the king for some small yearly rent, and the performance of such services as were originally laid upon the land at the donation thereof. For as the king gave to the great nobles, his immediate tenants, large possessions for ever, to hold of him for this or that service or rent; so they in time parcelled out to such others as they liked the same lands for rents and services as they thought good: and these services were by Littleton divided into two kinds, *chivalry* and *socage*; the first whereof was martial and military, the other rustic. Chivalry, therefore, was a tenure of service, whereby the tenant was obliged to perform some noble or military office unto his lord: and it was of two kinds; either *regal*, that is, held only of the king; or *common*, where held of a common person. That which might be held only of the king was called *servitium*, or *sergeantia*; and was again divided into *grand* and *petit* serjeanty. The grand serjeanty was where one held lands of the king by service, which he ought to do in his own person; as, to bear the king's banner or spear, to lead his host, to find men at arms to fight, &c. Petit serjeanty was when a man held lands of the king, to yield him annually some small thing towards his wars, as a sword, dagger, bow, &c. Chivalry that might be holden of a common person was termed *scutagium*, "*escuage*;" that is, service of the shield; which was either uncertain or certain.

Escuage uncertain, was likewise two-fold: first, where the tenant was bound to follow his lord, going in person to the king's wars, either himself, or sending a sufficient man in his place, there to be maintained at his expence, so long as was agreed upon between the lord and his first tenant at the granting of the fee; and the days of such service seem to have been rated by the quantity of land so holden: as if it extended to a whole knight's fee, then the tenant was to follow his lord 40 days; and if but to half a knight's fee, then 20 days; if a fourth part, then 10 days, &c. The other kind of this *escuage* was called *castle-ward*, where the tenant was obliged, by himself or some other, to defend a castle as often as it should come to his turn. And these were called *escu-*

age uncertain; because it was uncertain how often a Chivalry, man should be called to follow his lord to the wars, or to defend a castle, and what his charge would be therein.

Escuage certain, was where the tenure was set at a certain sum of money to be paid in lieu of such service; as that a man should pay yearly for every knight's fee 20s. for half a knight's fee 10s. or some like rate; and this service, because it is drawn to a certain rent, groweth to be of a mixed nature, not merely *socage*, and yet *socage* in effect, being now neither personal service nor uncertain. The tenure called chivalry had other conditions annexed to it: but there is a great alteration made in these things by the stat. 12. Car. 2. c. 24. whereby tenures by knight's service of the king, or any other person *in capite*, &c. and the fruits and consequences thereof, are taken away and discharged; and all tenures are to be construed and adjudged to be free and common *socage*, &c.

Court of CHIVALRY, a court formerly held before the lord high constable and earl marshal of England jointly, and having both civil and criminal jurisdiction: but since the attainder of Stafford Duke of Buckingham under Henry VIII. and the consequent extinguishment of the office of lord high constable, it hath usually, with respect to civil matters, been heard before the earl marshal only. This court, by stat. 13. Rich. II. c. 2. hath cognizance of contracts and other matters touching deeds of arms and war, as well out of the realm as in it. And from its sentences lies an immediate appeal to the king in person. This court was in great reputation in the times of pure chivalry; and afterwards during the English connections with the continent, by the territories which their princes held in France: but it is now grown almost entirely out of use, on account of the feebleness of its jurisdiction, and want of power to enforce its judgements; as it can neither fine nor imprison, not being a court of record.

1. The *civil* jurisdiction of this court of chivalry is principally in two points; the redressing injuries of honour, and correcting encroachments in matters of coat armour, precedence, and other distinctions of families. As a court of honour, it is to give satisfaction to all such as are aggrieved in that point; a point of a nature so nice and delicate, that its wrongs and injuries escape the notice of the common law, and yet are fit to be redressed somewhere. Such, for instance, as calling a man a *coward*, or giving him the lie; for which, as they are productive of no immediate damage to his person or property, no action will lie in the courts at Westminster: and yet they are such injuries as will prompt every man of spirit to demand some honourable amends; which, by the ancient law of the land, was given in the court of chivalry. But modern resolutions have determined, that how much soever a jurisdiction may be expedient, yet no action for words will at present lie therein. And it hath always been most clearly holden, that as this court cannot meddle with any thing determinable by common law, it therefore can give no pecuniary satisfaction or damages; in as much as the quantity and determination thereof is ever of common law cognizance. And therefore this court of chivalry can at most order reparation in point of honour; as, to compel

Chivalry
||
Chium.

compel the defendant *mendacium sibi ipsi imponere*, or to take the lie that he has given upon himself, or to make such other submission as the laws of honour may require. As to the other point of its civil jurisdiction, the redressing of usurpations and encroachments in matters of heraldry and coat armour; it is the business of this court, according to Sir Matthew Hale, to adjust the right and armorial ensigns, bearings, crests, supporters, pennons, &c.; and also rights of places or precedence, where the king's patent or act of parliament, which cannot be over-ruled by this court, have not already determined it. The proceedings of this court are by petition in a summary way: and the trial not by a jury of twelve men, but by witnesses, or by combat. But as it cannot imprison, not being a court of record; and as, by the resolutions of the superior courts, it is now confined to so narrow and restrained a jurisdiction; it has fallen into contempt. The marshalling of coat-armour, which was formerly the pride and study of all the best families in the kingdom, is now greatly disregarded; and has fallen into the hands of certain officers and attendants upon this court, called *heralds*, who consider it only as a matter of lucre, and not of justice: whereby such falsity and confusion have crept into their records (which ought to be the standing evidence of families, descents, and coat armour), that though formerly some credit has been paid to their testimony, now, even their common seal will not be received as evidence in any court of justice in the kingdom. But their original visitation books, compiled when progresses were solemnly and regularly made into every part of the kingdom, to inquire into the state of families, and to register such marriages and descents as were verified to them upon oath, are allowed to be good evidence of pedigrees.

2. As a *criminal* court, when held before the lord high constable of England jointly with the earl Marshal, it had jurisdiction over pleas of life and member, arising in matters of arms and deeds of war, as well out of the realm as within it. But the criminal as well as civil part of its authority is fallen into entire disuse: there having been no permanent high constable of England (but only *pro hac vice*, at coronations and the like), since the attainder and execution of Stafford Duke of Buckingham, in the 13th year of Henry VIII.; the authority and charge, both in war and peace, being deemed too ample for a subject; so ample, that when the chief justice Fineux was asked by King Henry VIII. how far they extended? he declined answering; and said, the decision of that question belonged to the law of arms, and not to the law of England.

CHIVES, in botany, are slender thread-like substances, generally placed within the blossom, and surrounding the *POINTALS*. They are formed of the woody substance of the plant.

CHIUM MARMOR, in the natural history of the ancients, the name of a black marble, called also the *lapis opsidianus*. It is very hard, and of a fine black; and, beside the many uses which the ancients put it to, is well known among our goldsmiths by the name of the *touchstone*; most of them being furnished with nothing better for this purpose than a piece of this: though the basalt, which might be had plentifully

enough, is greatly preferable for those uses; any black marble, however, that is tolerably hard, will do. There is a very fine and elegantly smooth marble, of a compact texture, and fine glossy black, but showing no glittering particles when fresh broken, as most of the black marbles do. It is extremely hard, and cuts with difficulty, but is capable of the highest polish of any marble. The ancients had it from Ethiopia and the island of Chios; we have it from Italy.

CHIUM Vinum, *Chian Wine*, or wine of the growth of the island of Chios, now Scio, is commended by Dioscorides as affording good nourishment, fit to drink, less disposed to intoxicate, endued with the virtue of restraining defluxions, and a proper ingredient in ophthalmic medicines. Hence Scribonius Largus directs the dry ingredients in collyria for the eyes to be made up with Chian wine.

CHIUN, or CHEVAN, in Hebrew antiquity. We meet with this word in the prophet Amos, cited in the Acts of the Apostles. St Luke reads the passage thus: "Ye took up the tabernacle of Moloch, and the star of your god Remphan, figures which ye made to worship them." The import of the Hebrew is as follows: "Ye have borne the tabernacle of your kings, and the pedestal (the *chiun*) of your images, the star of your gods, which ye made to yourselves." The Septuagint in all probability read *Repham* or *Revan*, instead of *Chiun* or *Chevan*, and took the pedestal for a god.

Some say that the Septuagint, who made their translation in Egypt, changed the word *Chiun* into that of *Remphan* because they had the same signification. M. Basnage, in his book intitled *Jewish Antiquities*, after having discoursed a good deal upon *Chion* or *Remphan*, concludes that Moloch was the sun, and *Chion*, *Chiun*, or *Remphan*, the moon.

CHLAMYS, in antiquity, a military habit worn by the ancients over the tunica. It belonged to the patricians, and was the same in the time of war that the toga was in the time of peace. This sort of gown was called *picca*, from the rich embroidery with figures in Phrygian work; and *purpurea*, because the ground-work was purple. The chlamydes of the emperors were all purple, adorned with a golden and embroidered border.

CHLOEIA, in antiquity, a festival celebrated at Athens in honour of Ceres, to whom, under the name *χλον*, i. e. *Grass*, they sacrificed a ram.

CHLORA, in botany, a genus of the monogynia order, belonging to the octandria class of plants. The calyx is octophyllous, the corolla monopetalous and octofid; the capsule unilocular, bivalved, and polyspermous.

CHLOROSIS, in medicine, a disease, commonly called the *green-sickness*, incident to young girls. See (the Index subjoined to) MEDICINE.

CHOCOLATE, in commerce, a kind of paste or cake prepared of certain ingredients, the basis of which is cacao. See CACAO.

The Indians, in their first making of chocolate, used to roast the cacao in earthen pots; and having afterwards cleared it of the husks, and bruised it between two stones, they made it into cakes with their hands. The Spaniards improved this method: when the cacao is properly roasted and well cleaned, they pound it in

Chium
||
Chocolate.

Chocolate a mortar, to reduce it into a coarse mass, which they afterwards grind on a stone till it be of the utmost fineness; the paste being sufficiently ground, is put quite hot into tin moulds, in which it congeals in a very little time. The form of these moulds is arbitrary: the cylindrical ones, holding two or three pounds, are the most proper; because the bigger the cakes are, the longer they will keep. Observe, that these cakes are very liable to take any good or bad scent, and therefore they must be carefully wrapt up in paper, and kept in a dry place. Complaints are made, that the Spaniards mix with the cacao nuts too great a quantity of cloves and cinnamon, besides other drugs without number, as musk, ambergrease, &c. The grocers of Paris use few or none of these ingredients: they only choose the best nuts, which are called *caracaca*, from the place from whence they are brought; and with these they mix a very small quantity of cinnamon, the freshest vanilla, and the finest sugar, but very seldom any cloves. In England, the chocolate is made of the simple cacao, excepting that sometimes sugar and sometimes vanilla is added.

Chocolate ready made, and cacao paste, are prohibited to be imported from any part beyond the seas. If made and sold in Great Britain, it pays inland duty 1s. 6d. *per lb.* avoirdupoise: it must be inclosed in papers containing one pound each, and produced at the excise-office to be stamped. Upon three days notice given to the officer of excise, private families may make chocolate for their own use, provided no less than half an hundred weight of nuts be made at one time.

The chocolate made in Portugal and Spain is not near so well prepared as the English, depending perhaps on the machine employed there, *viz* the double cylinder, which seems very well calculated for exact triture. If perfectly prepared, no oil appears on the solution. London chocolate gives up no oil like the foreign; and it also may, in some measure, depend on the thickness of the preparation. The solution requires more care than is commonly imagined. It is proper to break it down, and dissolve it thoroughly in cold water by milling it with the chocolate stick. If heat is applied, it should be done slowly: for, if suddenly, the heat will not only coagulate it, but separate the oil; and therefore much boiling after it is dissolved, is hurtful. Chocolate is commonly required by people of weak stomachs; but often rejected for want of proper preparation. When properly prepared, it is easily dissolved; and an excellent food where a liquid nutrient vegetable one is required, and is less flatulent than any of the farinacea.

Mr Henly, an ingenious electrician, has lately discovered that chocolate, fresh from the mill, as it cools in the tin-pans into which it is received, becomes strongly electrical; and that it retains this property for some time after it has been turned out of the pans, but soon loses it by handling. The power may be once or twice renewed by melting it again in an iron ladle, and pouring it into the tin pans as at first; but when it becomes dry and powdery, the power is not capable of being revived by simple melting: but if a small quantity of olive-oil be added, and well mixed with the chocolate in the ladle, its electricity will be completely re-

flored by cooling it in the tin pan as before. From Chocolate this experiment he conjectures, that there is a great affinity between phlogiston and the electric fluid, if indeed they be not the same thing.

CHOCOLATE-Nut Tree. See CACAO.

CHOENIX, *χοινίξ*, an ancient dry measure, containing the 48th part of a *medimnus*, or six bushels.

CHOERILUS, a tragic poet of Athens about the 64th olympiad. He wrote 150 tragedies, of which 13 had obtained the prize.—An historian of Samos.—Two other poets, one of whom was very intimate with Herodotus. He wrote a poem on the victory which the Athenians had obtained over Xerxes; and on account of the excellence of the composition he received a piece of gold for each verse from the Athenians. The other was one of Alexander's flatterers and friends.

CHOERINÆ, in antiquity, a kind of sea-shells, with which the ancient Greeks used to give their suffrage, or vote.

CHOIR, that part of the church or cathedral where choiristers sing divine service; it is separated from the chancel where the communion is celebrated, and also from the nave of the church where the people are placed: the patron is said to be obliged to repair the choir of the church. It was in the time of Constantine that the choir was separated from the nave. In the twelfth century, they began to inclose it with walls; but the ancient balustrades have been since restored, out of a view to the beauty of architecture.

CHOIR, in nunneries, is a large hall adjoining to the body of the church, separated by a grate, where the nuns sing the office.

CHOISI (Francis Timoleon de), dean of the cathedral of Bayeux, and one of the forty of the French academy, was born at Paris in 1644. In 1685, he was sent with the chevalier de Chaumont to the king of Siam, and was ordained priest in the Indies by the apostolical vicar. He wrote a great number of works, in a polite, florid, and easy style; the principal of which are, 1. Four dialogues on the Immortality of the Soul, &c. 2. Account of a voyage to Siam. 3. An Ecclesiastical History, in 11 vols, 4to. 4. Life of David, with an interpretation of the Psalms. 5. Life of Solomon, &c. He died at Paris in 1724.

CHOLEDOCHUS, in anatomy, a term applied to a canal, or duct, called also *ductus communis*; formed of the union of the porus bilarius and ductus cysticus. The word comes from *χολη*, *chole*; and *δισχομαι*, *I receive*, or *contain*.

The choledochus ductus, passing obliquely to the lower-end of the duodenum, serves to convey the bile from the liver to the intestines. See ANAT. n° 97.

CHOLER See BILE.

CHOLERA MORBUS, a sudden eruption or overflowing of the bile or bilious matters both upwards and downwards. See (the *Index* subjoined to) MEDICINE.

CHOMER, or OMER. See CORUS.

CHONDRILLA, in botany, a genus of the polygamia equalis order, belonging to the syngenesia class of plants; and in the natural method ranking under the 49th order, *Composita*. The receptacle is naked; the calyx calyculated; the pappus simple and stalked; the florets in a manifold series.

CHONDROPTERYGII, in ichthyology, a term for-

From Chocolate
||
Chondropterygii.

Chop-
Church
||
Chord.

formerly applied to the order of fishes now called *amphibia nantes* by Linnæus. See AMPHIBIA.

CHOP-CHURCH, or CHURCH-CHOPPER, a name, or rather nick-name, given to parsons who make a practice of exchanging benefices. See PERMUTATION.

Chop-church occurs in an ancient statute as a lawful trade or occupation; and some of the judges say it was a good addition. Brook holds that it was no occupation, but a thing permissible by law.

CHOPIN, or CHOPINE, a liquid measure used both in Scotland and France, and equal to half their pint. See PINT and MEASURE.

CHOPIN (Rene), a famous civilian born at Bailleul in Anjou in 1537. He was advocate in the parliament of Paris, where he pleaded for a long time with great reputation. He at last shut himself up in his closet; and composed many works, which have been collected together, and printed in 6 vols, folio. He died at Paris in 1606.

CHORAL, signifies any person that, by virtue of any of the orders of the clergy, was in ancient times admitted to sit and serve God in the choir.

Dugdale, in his history of St Paul's Church, says, that there were with the chorus formerly six vicars choral belonging to that church.

CHORASSAN, or KHORASSAN, a province of Persia adjoining to Usbec Tartary. This was the ancient Bactria, and the birth-place of Kouli Khan.

CHORAX, or CHARAX. See CHARACENE.

CHORAZIM, or CHORAZIN, (Luke, Matthew), a town of Galilee: whose wretched incredulity Christ deplores: now desolate, at two miles distance from Capernaum.

* See Cordage.

CHORD, or CORD, primarily denotes a slender rope or cordage*. The word is formed of the Latin, *chorda*, and that from the Greek, *χορδή*, a gut, whereof strings may be made.

CHORD, in geometry, a right line drawn from one part of an arch of a circle to another. Hence,

CHORD of an Arch, is a right line joining the extremes of that arch.

CHORD, in music, the union of two or more sounds uttered at the same time, and forming together an entire harmony.

The natural harmony produced by the resonance of a sounding body, is composed of three different sounds, without reckoning their octaves; which form among themselves the most agreeable and perfect chord that can possibly be heard: for which reason they are called, on account of their excellence, *perfect chords*. Hence, in order to render that harmony complete, it is necessary that each chord should at least consist of three sounds. The trio is likewise found by musicians to include the perfection of harmony; whether because in this all the chords, and each in its full perfection, are used; or, because upon such occasions as render it improper to use them all, and each in its integrity, arts have been successfully practised to deceive the ear, and to give it contrary persuasion, by deluding it with the principal sounds of each *chord*, in such a manner as to render it forgetful of the other sounds necessary to their completion. Yet the octave of the principal sound produces new relations, and new consonances, by the completion of the intervals: they commonly add this octave, to have the assem-

blage of all the consonances in one and the same *chord*; (See CONSONANCE.) Moreover, the addition of the dissonance (see DISCORD), producing a fourth sound superadded to the perfect chord, it becomes indispensably necessary, if we would render the chord full, that we should include a fourth part to express this dissonance. Thus, the series of chords can neither be complete nor connected but by means of four parts.

Chords are divided into perfect and imperfect. The *perfect chord* is that which we have lately described; which is composed of the fundamental sound below, of its third, its fifth, and its octave: they are likewise subdivided into major and minor, according as the thirds which enter into their composition are flat or sharp: (See INTERVAL.) Some authors likewise give the name of *perfect* to all chords, even to dissonances, whose fundamental sounds are below. *Imperfect chords* are those in which the sixth, instead of the fifth, prevails, and in general all those whose lowest are not their fundamental sounds. These denominations, which had been given before the fundamental bass was known, are now most unhappily applied: those of chords *direct* and *reversed*, are much more suitable in the same sense.

Chords are once more divided into consonances and dissonances. The chords denominated *consonances*, are the perfect chord, and its derivatives: every other chord is a *dissonance*.

A table of both, according to the system of M. Rameau, may be seen in Rousseau's Musical Dictionary, vol. I. p. 27.

After the table to which our readers have been remitted, Rousseau adds the following observations, which are at the same time so just and so important, that we should be very sorry if they escape the reader's attention.

At the words *harmony*, *fundamental bass*, *composition*, &c. he promises to treat concerning the manner of using all the chords to form regular harmony; and only adds, in this place, the subsequent reflections.

1. It is a capital error to imagine, that the methods of inverting the same chord are in all cases equally eligible for the harmony and for the expression. There is not one of these different arrangements but had its proper character. Every one feels the contrast between the softness of the false fifth, and the grating sound of the tritone, though the one of these intervals is produced by a method of inverting the other. With the seventh diminished, and the second redundant, the case is the same with the interval of the second in general use, and the seventh. Who does not feel how much more vocal and sonorous the fifth appears when compared with the fourth? The *chord* of the great sixth, and that of the lesser sixth minor, are two forms of the same fundamental *chord*: but how much less is the one harmonious than the other? On the contrary, the *chord* of the lesser sixth major is much more pleasing and cheerful than that of the false fifth. And only to mention the most simple of all *chords*, reflect on the majesty of the perfect chord, the sweetness of that which is called the chord of the sixth, and the insipidity of that which is composed of a sixth and a fourth; all of them, however, composed of the same sounds. In general, the redundant

Chords
||
Chorepiscopus.

intervals, the sharps in the higher part, are proper by their severity to express violent emotions of mind, such as anger and the rougher passions. On the contrary, flats in the higher parts, and diminished intervals, form a plaintive harmony, which melts the heart. There are a multitude of similar observations, of which when a musician knows how to avail himself, he may command at will the affections of those who hear him.

2. The choice of simple intervals is scarcely of less importance than that of the *chords*, with regard to the stations in which they ought to be placed. It is, for instance, in the lower parts that the fifth and octave should be used in preference; in the upper parts, the third and sixth are more proper. If you transpose this order, the harmony will be ruined even tho' the same *chords* are preserved.

3. In a word, the *chords* are rendered still more harmonious, by being approximated and only divided by the smallest practicable intervals, which are more suitable to the capacity of the ear than such as are remote. This is what we call *contracting* the harmony, an art which few composers have skill and abilities enough to put in practice. The limits in the natural compass of voices, afford an additional reason for lessening the distance of the intervals, which compose the harmony of the chorus, as much as possible. We may affirm, that a chorus is improperly composed, when the distance between the *chords* increases; when those who perform the different parts are obliged to scream; when the voices rise above their natural extent, and are so remotely distant one from the other that the perception of harmonical relations between them is lost.

We say likewise, that an instrument is in *concord* when the intervals between its fixed sounds are what they ought to be; we say in this sense, that the *chords* of an instrument are true or false, that it preserves or does not preserve its *chords*. The same form of speaking is used for two voices which sing together, or for two sounds which are heard at the same time, whether in unison or in parts.

CHORDS, or *CORDS*, of *Musical Instruments*, are strings, by the vibration of which the sensation of sound is excited, and by the divisions of which the several degrees of tone are determined.

CHORDEE, in medicine and surgery, a symptom attending a gonorrhœa, consisting in a violent pain under the frenum, and along the duct of the urethra, during the erection of the penis, which is incurvated downwards. These erections are frequent and involuntary.

CHOREASANCTI VITI. See *VITUS's Dance*.

CHOREPISCOPUS, an officer in the ancient church, about whose function the learned are extremely divided. The word comes from *χωρος*, a *region*, or *little country*, and *ἐπισκοπος*, a *bishop*, or *over-seer*.

The chorepiscopi were suffragan or local bishops, holding a middle rank between bishops and presbyters, and delegated to exercise episcopal jurisdiction within certain districts, when the boundaries of particular churches, over which separate bishops presided, were considerably enlarged. It is not certain when this office was first introduced: some trace it to the close of

Nº 78.

the first century; others tell us, that chorepiscopi were not known in the east till the beginning of the fourth century; and in the west about the year 439. They ceased both in the east and west in the tenth century.

CHOREPISCOPUS is also the name of a dignity still subsisting in some cathedrals, particularly in Germany; signifying the same with *chori episcopus*, or "bishop of the choir." The word, in this sense, does not come from *χωρος*, *place*, but *χορος*, *choir*, &c. In the church of Cologne, &c. the first chanter is called *chorepiscopus*.

CHOREUS, *χορευς*, a foot in the ancient poetry, more commonly called *trocheus*. See *TROCHEE*.

CHORIAMBUS, in ancient poetry, a foot consisting of four syllables, whereof the first and last are long, and the two middle ones are short; or, which is the same thing, it is made up of a trocheus and iambus: such is the word *nobilitas*.

CHORION, in anatomy, the exterior membrane which invests the foetus in the uterus. See *FOETUS*.

CHOROBATA, or CHOROBATES, a kind of water level among the ancients, of the figure of the letter T, according to Vitruvius's description.

CHOROGRAPHY, the art of making a map of some country or province.

Chorography differs from geography, as the description of a particular country differs from that of the whole earth; and from topography, as the description of a country is different from that of a town or district. See the articles *GEOGRAPHY*, *TOPOGRAPHY*, and *MAP*.

CHOROIDES, or CHOROEIDES, in anatomy, a term applied to several parts of the body; bearing some resemblance to the chorion. The word is formed from *χοριον*, *chorion*, and *ειδος*, *likeness*.

CHOROIDES is particularly used for the inner membrane which immediately invests the brain; so called as being intermingled with a great number of blood-vessels, like the *chorion*: but more usually denominated the *pia mater*, or *meninx tenuis*.

Plexus or *Lacis CHOROIDES*, is a knot of veins and arteries in the anterior ventricle of the brain, woven out of the branches of the carotid.

CHOROIDES is also applied to the inner and posterior tunic of the eye, immediately under the sclerotica. It is soft, thin, and black; and its inner or concave surface is very smooth and polished. It has its name from its being interspersed with vessels.

CHORUS, in dramatic poetry, one or more persons present on the stage during the representation, and supposed to be by-standers without any share in the action.

Tragedy in its origin was no more than a single chorus, who trod the stage alone, and without any actors, singing dithyrambics or hymns in honour of Bacchus. Thespis, to relieve the chorus, added an actor, who rehearsed the adventures of some of their heroes; and Æschylus, finding a single person too dry an entertainment, added a second, at the same time reducing the singing of the chorus, to make more room for the recitation. But when once tragedy began to be formed, the recitative, which at first was intended only as an accessory part to give the chorus a breathing time, became a principal part of the tragedy.

Chorepiscopus.
||
Chorus.

Chorus.
||
Chosroes.

dy. At length, however, the chorus became inserted and incorporated into the action: sometimes it was to speak; and then their chief, whom they called *coryphæus*, spoke in behalf of the rest: the singing was performed by the whole company; so that when the *coryphæus* struck into a song, the chorus immediately joined him.

The chorus sometimes also joined the actors in the course of the representation, with their complaints and lamentations on account of any unhappy accidents that befel them: but the proper function, and that for which it seemed chiefly retained, was to show the intervals of the acts: while the actors were behind the scenes, the chorus engaged the spectators; their songs usually turned on what was exhibited, and were not to contain any thing but what was suited to the subject, and had a natural connection with it; so that the chorus concurred with the actors for advancing the action. In the modern tragedies the chorus is laid aside, and the fiddles supply its place. M. Dacier looks on this retrenchment as of ill consequence, and thinks it robs tragedy of a great part of its lustre; he therefore judges it necessary to re-establish it, not only on account of the regularity of the piece, but also to correct, by prudent and virtuous reflections, any extravagances that might fall from the mouths of the actors when under any violent passion.

M. Dacier observed also, that there was a chorus, or *grex*, in the ancient comedy: but this is suppressed in the new comedy, because it was used to reprove vices by attacking particular persons; as the chorus of the tragedy was laid aside to give the greater probability to those kinds of intrigue which require secrecy.

CHORUS, in music, is when, at certain periods of a song, the whole company are to join the singer in repeating certain couplets or verses.

CHOSE, (*Fr.*) "a thing;" used in the common law with divers epithets; as *chose local*, *chose transitory*, and *chose in action*. *Chose local* is such a thing as is annexed to a place, as a mill and the like; *chose transitory* is that thing which is moveable, and may be taken away, or carried from place to place; and *chose in action* is a thing incorporeal, and only a *right*, as an obligation for debt, annuity, &c. And generally all causes of suit for any debt, duty, or wrong, are to be accounted choses in action: and it seems, chose in action may be also called *chose in suspense*; because it hath no real existence or being, nor can properly be said to be in our possession.

CHOSROES I. the Great, king of Persia, after his father Cabades, A. D. 532. He made peace with the Romans; but broke it the third year, and forced Justinian to a disadvantageous peace. Afterward, he was so swelled with his victories, as to bid the emperor's ambassador follow him for audience to Cæsarea: but Tiberius sent an army under Justinian; who made himself master of the country, and put Chosroes to death in 586.

CHOSROES II. His subjects put his father Hormisdas in prison, and the son upon the throne of Persia. He used his father tenderly at first; but afterwards caused him to be put to death. This, together with his killing some of the nobility, obliged him to fly: he gave his horse the bridle, which carried him into a

VOL. IV. Part II.

town of the Romans, where Mauricius the emperor received him kindly, and sent an army under Narfes, which set him again upon the throne. He took Jerusalem; after this he made himself master of Libya and Egypt, and carried Carthage. Heraclius sued for peace; which was offered him on condition, *That he and his subjects should deny Jesus Christ*: Hereupon Heraclius attacked him with success, and put him to flight. His own son pursued him, and he was starved in prison in 627.

CHOUCH, in ornithology, the trivial name of a species of CORVUS.

CHOUS, in the eastern military orders, the title of the messengers of the divan of Janisaries. There are several degrees of honour in this post. When a person is first advanced to it, he is called a *cuchuk*, or little *chous*; after this he is advanced to be the *alloy chous*; that is, the messenger of ceremonies; and from this, having passed through the office of *petelma*, or procurator of the effects of the body, he is advanced to be the *bas chous*.

CHOWDER-BEER, a provincial phrase of Devonshire, denoting a cheap and easily prepared drink, highly commended for preventing the scurvy in long voyages, or for the cure of it where it may have been contracted. It is prepared in the following manner: Take twelve gallons of water, in which put three pounds and a half of black spruce: boil it for three hours, and having taken out the fir or spruce, mix with the liquor seven pounds of melasses, and just boil it up; strain it through a sieve, and when milk warm put to it about four spoonfuls of yeast to work it. In two or three days stop the bung of the cask; and in five or six days, when fine, bottle it for drinking. Two gallons of melasses are sufficient for an hoghead of liquor; but if melasses cannot be procured, treacle or coarse sugar will answer the purpose.

CHREMnitz, the principal of the nine-towns in Upper Hungary, situated about 68 miles north-east of Presburg, and subject to the house of Austria. E. Long. 19. N. Lat. 48. 45.

CHRENECRUDA, a term occurring in writers of the middle age, and expressing a custom of those times; but its signification is doubtful. It is mentioned in *Lege Salica*, Tit. 61. which says, he who kills a man, and hath not wherewithal to satisfy the law or pay the fine, makes oath that he has delivered up every thing he was possessed of; the truth of which must be confirmed by the oaths of 12 other persons. Then he invites his next relations by the father's side to pay off the remainder of the fine, having first made over to them all his effects by the following ceremony. He goes into his house, and taking in his hand a small quantity of dust from each of the four corners, he returns to the door, and with his face inwards throws the dust with his left hand over his shoulders upon his nearest of kin. Which done, he strips to his shirt; and coming out with a pole in his hand, jumps over the hedge. His relations, whether one or several, are upon this obliged to pay off the composition for the murder. And if these (or any one of them) are not able to pay, *iterum super illum chrenecruda, qui pauperior est, jactat, et ille totam legem componat*. Whence it appears, that *chrenecruda jactare*, is the same with throwing the dust, gathered from the four corners of the house.

cruda.

Chrism
||
Christ.

house. Goldastus and Spelman translate it *viridem herbam*, "green grass," from the German *gruen kraut*, or from the Dutch *groen*, "green," and *gruid*, "grass." Wendelinus is of a contrary opinion, who thinks that by this word *denotari purificationis approbationem*, from *ghrein*, "pure, chaste, clean;" and *keuren*, "to prove;" so that it must refer to the oaths of the twelve jurors. Be this as it will, king Childebert reformed this law by a decree, chap. 15. both because it favoured of pagan ceremonies, and because several persons were thereby obliged to make over all their effects: *De chrenecruda lex quam paganorum tempore observabant, deinceps nunquam valeat, quia per ipsam cecidit multorum potestas.*

CHRISM (from *χρισω*, *I anoint*), oil consecrated by the bishop, and used in the Romish and Greek churches, in the administration of baptism, confirmation, ordination, and extreme unction, which is prepared on holy Thursday with much ceremony. In Spain it was anciently the custom for the bishop to take one third of a sol for the chrism distributed to each church, on account of the balsam that entered its composition.

Du Cange observes, that there are two kinds of chrism; the one prepared of oil and balsam, used in baptism, confirmation, and ordination; the other of oil alone, consecrated by the bishop, used anciently for the catechumens, and still in extreme unction. The Maronites, before their reconciliation with Rome, besides oil and balsam, used musk, saffron, cinnamon, roses, white frankincense, and several other drugs mentioned by Rynaldus, in 1541, with the doses of each. The Jesuit Dandini, who went to mount Libanus in quality of the pope's nuncio, ordained, in a synod held there in 1596, that chrism for the future should be made only of two ingredients, oil and balsam; the one representing the human nature of Jesus Christ, the other his divine nature. The action of imposing the chrism is called *chrismation*: this the generality of the Romish divines hold to be the next matter of the sacrament of confirmation.

The chrismation in baptism is performed by the priest; that in confirmation by the bishop; that in ordination, &c. is more usually styled *unction*.

CHRISM Pence, *CHRISMATIS Denarii*, or *CHRISMALES Denarii*, a tribute anciently paid to the bishop by the parish-clergy, for their chrism, consecrated at Easter for the ensuing year: this was afterwards condemned as simoniacal.

CHRISOM, *CHRISMALE*, was anciently the face-cloth or piece of linen laid over the child's head when it was baptized. Whence, in our bills of mortality, children who die in the month are called *chrifoms*. The time between the child's birth and baptism was also called *chrifomus*.

CHRIST, an appellation synonymous with *Messiah*, usually added to Jesus: and, together therewith, denominating the Saviour of the world. See CHRISTIANITY and MESSIAH.

The word *χρισω* signifies *anointed*, from *χρισω*, *imungo*, "I anoint." Sometimes the word *Christ* is used singly, by way of *antonomasis*, to denote a person sent from God, as an anointed prophet, king, or priest.

Order of *CHRIST*, a military order, founded by Dionysius I. king of Portugal, to animate his nobles against the Moors.—The arms of this order are gules, patriarchal cross, charged with another cross argent: they

had their residence at first at Castromarin; afterwards they removed to the city of Thomar, as being nearer to the Moors of Andalusia, and Estremadura.

CHRIST is also the name of a military order in Livonia, instituted in 1205 by Albert bishop of Riga. The end of this institution was to defend the new Christians, who were converted every day in Livonia, but were persecuted by the heathens. They wore on their cloaks a sword with a cross over it, whence they were also denominated *brothers of the sword*.

CHRIST-Burgh, a town of Poland, near the lake Drausen, and about three Polish miles from Marienburgh.

CHRIST-Church, a borough-town of Hampshire, 30 miles south-west of Winchester, near the sea-coast. W. Long. 2. N. Lat. 50. 40. It sends two members to parliament.

CHRIST-Thorn, in botany. See RHAMNUS.

CHRISTIAN. See CHRISTIANITY and CHRISTIANS.

Most CHRISTIAN King, one of the titles of the king of France.

The French antiquaries trace the origin of this appellation up to Gregory the Great, who, writing a letter to Charles Martel, occasionally gave him that title, which his successors have since retained.

CHRISTIAN Religion, that instituted by Jesus Christ. See CHRISTIANITY.

CHRISTIANITY, the religion of Christians. The word is analogically derived, as other abstracts from their concretes, from the adjective *Christian*. This again is derived from the name *χρισος*, *Christus*, from the word *χρισω*, *I anoint*. Christ is called *the anointed*, from a custom which extensively prevailed in antiquity, and was originally said to be of divine institution, of anointing persons in the sacerdotal or regal character, as a public signal of their consecration to their important offices, and as a testimony that heaven itself was the guarantee of that relation which then commenced between the persons thus consecrated and their subordinates.

The disciples of Jesus, after the death of their teacher, had for some time been called *Nazarenes*, from Nazareth in Galilee where he dwelt; which afterwards became the designation of a particular sect. They, who adopted the principles and professed the religion which he taught, were first distinguished by the name of *Christians* at Antioch. That profession, and those doctrines, we now proceed to delineate with as much perspicuity as the limits of our plan will admit, yet with the conciseness which a work so multi-form and extensive requires.

When a Christian is interrogated concerning the nature and foundation of his faith and practice, his ultimate reference, his last appeal, is to the facts, the doctrines, and the injunctions, contained in the books of the Old and New Testament. From these, therefore, and from these alone, must every fair account, or the materials of which it is composed, be extracted or deduced. Other formularies, or confessions of faith, may, according to the Christian, deserve more or less attention, as they are more or less immediately contained or implied in the scriptures. But whatever is not actually expressed in, or deduced by fair and necessary consequence from, these writings, must be regarded as merely human; and can have no other title to

to our assent and observation than what they derive from their conformity with the scriptures, with the dictates and feelings of a reformed and cultivated mind, or with those measures which are found expedient and useful in human life. But as those books, from whence the Christian investigates his principles of belief and rules of conduct, have been variously interpreted by different professors and commentators, these diversities have given birth to a multiplicity of different sects. It cannot, therefore, be expected, that any one who undertakes to give an account of Christianity, should comprehend all the writings and opinions which have been propagated and exhibited by historical, systematical, or polemical authors. These, if at all contained in such a work as this, should be ranged under their proper articles, whether scientific, controversial, or biographical. It is our present business, if possible, to confine ourselves to a detail of such facts and doctrines as, in the strict and primitive sense of the word, are *catholic*, or in other expressions, to such as uniformly have been, and still are, recognised and admitted by the whole body of Christians.

4
Account of
Christianity,
whence
deducible.

We have already said that these, or at least the greatest number of them, appeal to the scriptures of the Old and New testament as the ultimate standard, the only infallible rule of faith and manners. If you ask them, by what authority these books claim an absolute right to determine the consciences and understandings of men with regard to what they should believe and what they should do? they will answer you, that all scripture, whether for doctrine, correction, or reproof, was given by immediate inspiration from God.

5
The nature
of its evi-
dences.

If again you interrogate them how those books, which they call *Scripture*, are authenticated? they reply, that the evidences by which the Old and New Testament are proved to be the Word of God, are either external or internal. The *external* may again be divided into direct or collateral. The direct evidences are such as arise from the nature, consistency, and probability, of the facts; and from the simplicity, uniformity, competency, and fidelity, of the testimonies by which they are supported. The collateral events, are either the same occurrences supported by Heathen testimonies, or others which concur with and corroborate the history of Christianity. Its *internal* evidences arise either from its exact conformity with the character of God, from its aptitude to the frame and circumstances of man, or from those supernatural convictions and assistances which are impressed on the mind by the immediate operation of the divine Spirit. These can only be mentioned in a cursory manner in a detail so concise as the present.

6
How Chri-
stianity is
supported
by facts.

Such facts as are related in the history of his religion, the Christian asserts to be not only consistent each with itself, but likewise one with another. Hence it is, that, by a series of antecedents and consequences, they corroborate each other, and form a chain which cannot be broken but by an absolute subversion of all historical authenticity. Nor is this all: for, according to him, the facts on which Christianity is founded, not only constitute a series of themselves, but are likewise in several periods the best resources for supplying the chasms in the history of our nature,

and preserving the tenor of its annals entire. The facts themselves are either natural or supernatural. By natural facts we mean such occurrences as happen or may happen from the various operations of mechanical powers, or from the interposition of natural agents without higher assistants. Such are all the common occurrences of history, whether natural, biographical, or civil: By supernatural facts, we mean such as could not have been produced without the interposition of Deity, or at least of powers superior to the laws of mechanism or the agency of embodied spirits. Among these may be reckoned the immediate change of water into wine, the instantaneous cure of diseases without the intervention of medicine, the resuscitation of the dead, and others of the same kind. In this order of occurrences may likewise be numbered the exertions and exhibitions of prophetic power, where the persons by whom these extraordinary talents were displayed could neither by penetration nor conjecture unravel the mazes of futurity, and trace the events of which they spoke from their primary causes to their remote completions. So that they must have been the passive organs of some superior Being, to whom the whole concatenation of causes and effects which operate from the origin to the consummation of nature, was obvious at a glance of thought.

It has already been hinted, that the facts which we have called *natural*, not only agree with the analogy of human events, and corroborate each other, but in a great many emergencies nobly illustrate the history of nature in general. For this a Christian might offer one instance, of which philosophy will not perhaps be able to produce any tolerable solution, without having recourse to the facts upon which Christianity is founded. For if mankind were originally descended from one pair alone, how should it have happened that long before the date of authentic history every nation had its own distinct language? Or if it be supposed, as some late philosophers have maintained, that man is an indigenous animal in every country; or, that he was originally produced in, and created for, each particular soil and climate which he inhabits; still it may be demanded, whence the prodigious multiplicity, the immense diversity, of languages? Is the language of every nation intuitive, or were they dictated by exigences, and established by convention? If the last of these suppositions be true, what an immense period of time must have passed? How many revolutions of material and intellectual nature must have happened? What accessions of knowledge, refinement, civilization, must human intercourse have gained before the formation and establishment even of the most simple, imperfect, and barbarous language? Why is a period so vast, obliterated so entirely as to escape the retrospect of history, of tradition, and even of fable itself? Why was the acquisition and improvement of other arts so infinitely distant from that of language, that the æra of the latter is entirely lost, whilst we can trace the former from their origin through the various gradations of their progress.

These difficulties, inextricable by all the lights of history or philosophy, this more than Cimmerian darkness, is immediately dissipated by the Mosaic account of the confusion of tongues; wisely intended to separate

Christianity.

rate the tribes of men one from another, to replenish the surface of the globe, and to give its multiplied inhabitants those opportunities of improvement which might be derived from experiment and industry, variously exerted, according to the different situations in which they were placed, and the different employments which these situations dictated. Thus the time of nature's existence is limited to a period within the ken of human intellect. Thus whatever has happened might have happened during the present mode of things; whereas, if we deduce the origin and diversity of language from a period so remotely distant as to be absolutely lost, and entirely detached from all the known occurrences and vicissitudes of time, we must admit the present forms and arrangements of things to have subsisted perhaps for a much longer duration than any mechanical philosopher will allow to be possible. Other instances equally pregnant with conviction might be multiplied; but, precluded by the limits of our plan, we proceed to a single observation upon the facts which have been termed *supernatural*.

9.
Miracles,
how con-
ducive to
prove the
truth of
Christiani-
ty.

Of those changes which happen in sensible objects, sensation alone can be judge. Reason has nothing to do in the matter. She may draw conclusions from the testimonies of sense, but can never refute them. If, therefore, our senses inform us that snow is white, in vain would the most learned and subtle philosopher endeavour to convince us that it was of a contrary colour. He might confound us, but never could persuade us. Such changes, therefore, as appear to happen in sensible objects, must either be real or fallacious. If real, the miracle is admitted; if fallacious, there must be a cause of deception equally unaccountable from the powers of nature, and therefore equally miraculous. If the veracity or competency of the witnesses be questioned, the Christian answers, that they must be competent, because the facts which they relate are not beyond their capacity to determine. They must likewise be faithful, because they had no secular motives for maintaining, but many for suppressing or disguising, what they testified. Now the Christian appeals to the whole series of history and experience, whether such a man is or can be found, as will offer a voluntary, solemn, and deliberate sacrifice of truth at the shrine of caprice. But such facts as after a long continuance of time have been found exactly agreeable to predictions formerly emitted, must supersede the fidelity of testimony, and infallibly prove that the event was known to the Being by whom it was foretold. In vain has it been urged, that prophecies are ambiguous and equivocal. For though they may prefigure subordinate events, yet if the grand occurrences to which they ultimately relate, can alone fulfil them in their various circumstances, and in their utmost extent, it is plain, that the Being by whom they were revealed must have been actually prescient of those events, and must have had them in view when the predictions were uttered. For this see a learned and ingenious Dissertation on the Credibility of Gospel-history, by Dr M^r Knight; where the evidences urged by the Christian in defence of his tenets, which appear detached and scattered through innumerable volumes, are assembled and arranged in such a manner as to derive strength and lustre from the method in which they are disposed, without diminishing the

10
Prophecy
evident by
its own na-
ture inde-
pendent of
its vehicles.

force of each in particular. See also the works of Dr Hurd: consult likewise those of Newton, Sherlock, Chandler, &c. For the evidences of those preternatural facts which have been termed *miracles*, the reader may peruse a short but elegant and conclusive defence of these astonishing phenomena, in answer to Mr Hume, by the Rev. George Campbell, D. D.

It must be obvious to every reflecting mind, that whether we attempt to form the idea of any religion *a priori*, or contemplate those which have been already exhibited, certain facts, principles, or *data*, must be pre-established, from whence will result a particular frame of mind and course of action suitable to the character and dignity of that Being by whom the religion is enjoined, and adapted to the nature and situation of those agents who are commanded to observe it. Hence *Christianity* may be divided into *credenda* or doctrines, and *agenda* or precepts.

As the great foundation of his religion, therefore, the Christian believes the existence and government of one eternal and infinite Essence, which for ever retains in itself the cause of its own existence, and inherently possesses all those perfections which are compatible with its nature: such are, its almighty power, omniscient wisdom, infinite justice, boundless goodness, and universal presence. In this indivisible essence the Christian recognises three distinct subsistences, yet distinguished in such a manner as not to be incompatible with essential unity or simplicity of being. Nor is their essential union incompatible with their personal distinction. Each of them possesses the same nature and properties to the same extent. As, therefore, they are constituent of one God, if we may use the expression, there is none of them subordinate, none supreme. The only way by which the Christian can discriminate them is, by their various relations, properties, and offices. Thus the Father is said eternally to beget the Son, the Son to be eternally begotten of the Father, and the Holy Ghost eternally to proceed from both.

This infinite Being, though absolutely independent and for ever sufficient for his own beatitude, was graciously pleased to create an universe replete with inferior intelligences, who might for ever contemplate and enjoy his glory, participate his happiness, and imitate his perfections. But as freedom of will is essential to the nature of moral agents, that they may co-operate with God in their own improvement and happiness, so their natures and powers are necessarily limited, and by that constitution rendered peccable. This degeneracy first took place in a rank of intelligence superior to man. But guilt is never stationary. Impatient of itself, and cursed with its own feelings, it proceeds from bad to worse, whilst the poignancy of its torments increases with the number of its perpetrations. Such was the situation of Satan and his apostate angels. They attempted to transfer their turpitude and misery to man; and were, alas! but too successful. Hence the heterogeneous and irreconcilable principles which operate in his nature. Hence that inexplicable medley of wisdom and folly, of rectitude and error, of benevolence and malignity, of sincerity and fraud, exhibited through his whole conduct. Hence the darkness of his understanding, the depravity of his will, the pollution of his heart, the irregularity

11

gions.

12
Christian
theology.

Christia-
nity.

regularity of his affections, and the absolute subversion of his whole internal economy. These seeds of perdition soon ripened into overt acts of guilt and horror. All the hostilities of nature were confronted, and the whole sublunary creation became a theatre of disorder and mischief.

Here the Christian once more appeals to fact and experience. If these things are so; if *man* is the vessel of guilt and the victim of misery; he demands how this constitution of things can be accounted for? how can it be supposed, that a being so wicked and unhappy should be the production of an infinitely perfect Creator? He therefore insists, that human nature must have been disarranged and contaminated by some violent shock; and that, of consequence, without the light diffused over the face of things by Christianity, all nature must remain an inscrutable and inexplicable mystery.

To redress these evils, to re-establish the empire of virtue and happiness, to restore the nature of man to its primitive rectitude, to satisfy the remonstrances of infinite justice, to purify every original or contracted stain, to expiate the guilt and destroy the power of vice, the eternal Son of God, the second Person of the sacred Trinity, the Logos or Divine Word, the Redeemer or Saviour of the world, the Immanuel or God with us, from whom Christianity takes its name, and to whom it owes its origin, descended from the bosom of his Father; assumed the human nature; became the representative of man; endured a severe probation in that character; exhibited a pattern of perfect righteousness; and at last ratified his doctrine, and fully accomplished all the ends of his mission, by a cruel, unmerited, and ignominious death. Before he left this world, he delivered the doctrine of human salvation, and the rules of human conduct, to his apostles, whom he empowered to instruct the world in all that concerned their eternal felicity, and whom he invested with miraculous gifts to ascertain the reality of what they taught. To them he likewise promised another comforter, even the Divine Spirit, who should relume the darkness, console the woes, and purify the stains, of human nature. Having remained for a part of three days under the power of death, he arose again from the grave, discovered himself to his disciples, conversed with them for some time, then re-ascended to heaven; from whence the Christian expects him, according to his promise, to appear as the Sovereign Judge of the living and the dead, from whose awards there is no appeal, and by whose sentence the destiny of the pious and the wicked shall be eternally fixed.

Soon after his departure to the right hand of his Father, where, in his human nature, he sits supreme of all created beings, and invested with the absolute administration of heaven and earth, the Spirit of grace and consolation descended on his apostles with visible signatures of divine power and presence. Nor were his salutary operations confined to them, but extended to all the rational world, who did not by obstinate guilt repel his influences, and provoke him to withdraw them. These, indeed, were less conspicuous than at the glorious æra when they were visibly exhibited in the persons of the apostles. But though his

energy is less observable, it is by no means less effectual to all the purposes of grace and mercy.

The Christian is convinced, that there is and shall continue to be a society upon earth, who worship God as revealed in Jesus Christ; who believe his doctrines; who observe his precepts; and who shall be saved by his death, and by the use of these external means of salvation which he hath appointed.

These are few and simple. The sacraments of baptism and the eucharist, the interpretation and application of scripture, the habitual exercise of public and private devotion, are obviously calculated to diffuse and promote the interests of truth and virtue, by superinducing the salutary habits of faith, love, and repentance.

The Christian is firmly persuaded, that at the consummation of things, when the purposes of providence in the various revolutions of progressive nature are accomplished, the whole human race shall once more issue from their graves; some to immortal felicity, from the actual perception and enjoyment of their Creator's presence; others to everlasting shame and misery.

The two grand principles of action, according to the Christian, are, The love of God, which is the sovereign passion in every perfect mind; and the love of man, which regulates our actions according to the various relations in which we stand, whether to communities or individuals. This sacred connection can never be totally extinguished by any temporary injury. It ought to subsist in some degree even amongst enemies. It requires that we should pardon the offences of others, as we expect pardon for our own; and that we should no farther resist evil than is necessary for the preservation of personal rights and social happiness. It dictates every relative and reciprocal duty between parents and children, masters and servants, governors and subjects, friends and friends, men and men. Nor does it merely enjoin the observation of equity, but likewise inspires the most sublime and extensive charity, a boundless and disinterested effusion of tenderness for the whole species, which feels their distress and operates for their relief and improvement. These celestial dispositions, and the different duties which are their natural exertions, are the various gradations by which the Christian hopes to attain the perfection of his nature and the most exquisite happiness of which it is susceptible.

Such are the speculative, and such the practical principles of Christianity. From the former, its votaries contend, that the origin, economy, and revolutions of intelligent nature alone can be rationally explained. From the latter, they assert, that the nature of man, whether considered in its individual or social capacity, can alone be conducted to its highest perfection and happiness. With the determined Atheists they scarcely deign to expostulate. For, according to them, philosophers who can deduce the origin and constitution of things from casual rencounters or mechanical necessity, are capable of deducing any conclusion from any premises. Nor can a more glaring instance of absurdity be produced, than the idea of a contingent or self-originated universe. When Deists and other sectarians upbraid them with mysterious

rious or incompatible principles, they without hesitation remit such cavillers to the creed of natural religion. They demand why any reasoner should refuse to believe three distinct subsistences in one indivisible essence, who admits that a being may be omnipresent without extension; or that he can impress motion upon other things, whilst he himself is necessarily immoveable. They ask the sage, why it should be thought more extraordinary, that the Son of God should be sent to this world, that he should unite the human nature to his own, that he should suffer and die for the relief of his degenerate creatures, than that an existence whose felicity is eternal, inherent, and infinite, should have any motive for creating beings exterior to himself? Is it not, says the Christian, equally worthy of the divine interposition to restore order and happiness where they are lost, as to communicate them where they never have been? Is not infinite goodness equally conspicuous in relieving misery as in diffusing happiness? Is not the existence of what we call evil in the world, under the tuition of an infinitely perfect Being, as inscrutable as the mean exhibited by Christianity for its abolition? Vicarious punishment, imputed guilt and righteousness, merit or demerit transferred, are certainly not less reconcileable to human reason, *a priori*, than the existence of vice and punishment in the productions of infinite wisdom, power, and goodness: particularly when it is considered, that the virtues exerted and displayed by a perfect Being in a state of humiliation and suffering, must be meritorious, and may therefore be rewarded by the restored felicity of inferior creatures, in proportion to their glory and excellence; and that such merit may apply the blessings which it has deserved, in whatever manner, in whatever degree, and to whomsoever it pleases, without being under any necessity to violate the freedom of moral agents, in recalling them to the paths of virtue and happiness by a mechanical and irresistible force.

16
Miraculous
as possible,
and per-
haps as ne-
cessary, as
natural e-
vents.

It will be granted to philosophy by the Christian, that as no theory of mechanical nature can be formed without presupposing sacred and established laws from which she ought rarely or never to deviate, so in fact she tenaciously pursues these general institutions, and from their constant observance result the order and regularity of things. But he cannot admit, that the important ends of moral and intellectual improvement may be uniformly obtained by the same means. He affirms, that if the hand of God should either remain always entirely invisible, or at least only perceptible in the operation of second causes, intelligent beings would be apt in the course of time to resolve the interpositions of Deity into the general laws of mechanism; to forget his connection with nature, and consequently their dependence upon him. Hence, according to the dictates of common sense, and to the unanimous voice of every religion in every age or clime, for the purposes of wisdom and benevolence, God may not only control, but has actually controlled, the common course and general operations of nature. So that, as in the material world the law of *cause and effect* is generally and scrupulously observed for the purposes of natural subsistence and accommodation; thus suspenses and changes of that universal law are equally necessary

for the advancement of moral and intellectual perfection.

But the disciple of Jesus not only contends, that no system of religion has ever yet been exhibited so consistent with itself, so congruous to philosophy and the common sense of mankind, as Christianity; he likewise avers, that it is infinitely more productive of real and sensible consolation than any other religious or philosophical tenets, which have ever entered into the soul, or been applied to the heart of man. For what is death to that mind which considers eternity as the career of its existence? What are the frowns of fortune to him who claims an eternal world as his inheritance? What is the loss of friends to that heart which feels, with more than natural conviction, that it shall quickly rejoin them in a more tender, intimate, and permanent intercourse than any of which the present life is susceptible? What are the fluctuations and vicissitudes of external things to a mind which strongly and uniformly anticipates a state of endless and immutable felicity? What are mortifications, disappointments, and insults, to a spirit which is conscious of being the original offspring and adopted child of God; which knows that its omnipotent Father will, in proper time, effectually assert the dignity and privileges of its nature? In a word, as earth is but a speck of creation, as time is not an instant in proportion to eternity, such are the hopes and prospects of the Christian in comparison of every sublunary misfortune or difficulty. It is therefore, in his judgment, the eternal wonder of angels, and indelible opprobrium of man, that a religion so worthy of God, so suitable to the frame and circumstances of our nature, so consonant to all the dictates of reason, so friendly to the dignity and improvement of intelligent beings, pregnant with genuine comfort and delight, should be rejected and despised. Were there a possibility of suspense or hesitation between this and any other religion extant, he could freely trust the determination of a question so important to the candid decision of real virtue and impartial philosophy.

Mr Gibbon, in his History of the Decline and Fall of the Roman Empire, mentions five secondary causes to which he thinks the propagation of Christianity, and all the remarkable circumstances which attended it, may be with good reason ascribed. He seems to insinuate, that Divine Providence did not act in a singular or extraordinary manner in disseminating the religion of Jesus through the world; and that, if every other argument which has been adduced to prove the sacred authority of this religion can be parried or refuted, nothing can be deduced from this source to prevent it from sharing the same fate with other systems of superstition. The causes of its propagation were in his opinion founded on the principles of human nature and the circumstances of society. If we ascribe not the propagation of Mahometism, or of the doctrines of Zerdust, to an extraordinary interposition of divine providence, operating by an unperceived influence on the dispositions of the human heart, and controuling and confounding the ordinary laws of nature; neither can we, upon any reasonable grounds, refer the promulgation of Christianity to such an interposition.

The

Christianity.

19
The causes.

The secondary causes to which he ascribes these effects are, 1. The inflexible and intolerant zeal of the Christians; derived from the Jewish religion, but purified from the narrow and unsocial spirit which, instead of inviting, deterred the Gentiles from embracing the law of Moses. 2. The doctrine of a future life improved by every additional circumstance which could give weight and efficacy to that important truth. 3. The miraculous powers ascribed to the primitive church. 4. The pure and austere morals of the Christians. 5. The union and discipline of the Christian republic, which gradually formed an independent and increasing state in the heart of the Roman empire.

20
Cause I.

In pointing out the connection between the *first* of these causes and the effects which he represents as arising from it, this learned and ingenious writer observes, that the religion of the Jews does not seem to have been intended to be propagated among the Heathens, and that the conversion of proselytes was rather accidental than consistent with the purport and the general spirit of the institutions of Judaism. The Jews were, of consequence, studious to preserve themselves a peculiar people. Their zeal for their own religion was intolerant, narrow, and unsocial.

In Christianity, when it made its appearance in the world, all the better part of the predominant spirit of Judaism was retained; but whatever might have a tendency to confine its influence within narrow limits was laid aside. Christians were to maintain the doctrines and adhere to the institutions of their religion with sacred fidelity. They were not to violate their allegiance to Jesus by entertaining or professing any reverence for Jupiter or any other of the Heathen deities; it was not even necessary for them to comply with the positive and ceremonial institutions of the law of Moses,—although these were acknowledged to have been of divine origin. The zeal, therefore, which their religion inculcated, was inflexible. It was even intolerant: for they were not to content themselves with professing Christianity and conforming to its laws; they were to labour with unremitting assiduity, and to expose themselves to every difficulty and every danger, in converting others to the same faith.

But the same circumstances which rendered it thus intolerant, communicated to it a more liberal and a less unsocial spirit than that of Judaism. The religion of the Jews was intended only for a few tribes: Christianity was to become a catholic religion; its advantages were to be offered to all mankind.

All the different sects which arose among the primitive Christians uniformly maintained the same zeal for the propagation of their own religion, and the same abhorrence for every other. The Orthodox, the Ebionites, the Gnostics, were all equally animated with the same exclusive zeal, and the same abhorrence of idolatry, which had distinguished the Jews from other nations.

21
Observations in answer.

Such is the general purport of what Mr Gibbon advances concerning the influence of the first of those secondary causes in the propagation of Christianity. It would be uncandid to deny, that his statement of facts appears to be, in this instance, almost fair, and his deductions tolerably logical. The first Christians were remarkable for their detestation of idolatry, and for the generous disinterested zeal with which they laboured to convert others to the same faith. The first of these principles,

no doubt, contributed to maintain the dignity and the purity of Christianity; and the second to disseminate it through the world. But the facts which he relates are scarce consistent throughout. He seems to represent the zeal of the first Christians as so hot and intolerant, that they could have no social intercourse with those who still adhered to the worship of Heathen deities. In this case, how could they propagate their religion? Nay, we may even ask, How could they live? If they could not mingle with the Heathens in the transactions either of peace or war; nor witness the marriage or the funeral of the dearest friend, if a Heathen; nor practise the elegant arts of music, painting, eloquence, or poetry; nor venture to use freely in conversation the language of Greece or of Rome;—it is not easy to see what opportunities they could have of disseminating their religious sentiments. If, in such circumstances, and observing rigidly such a tenor of conduct, they were yet able to propagate their religion with such amazing success as they are said to have done; they must surely either have practised some wondrous arts unknown to us, or have been assisted by the supernatural operation of divine power.

But all the historical records of that period, whether sacred or profane, concur to prove, that the primitive Christians in general did not retire with such religious horror from all intercourse with the Heathens. They refused not to serve in the armies of the Roman empire: they appealed to Heathen magistrates, and submitted respectfully to their decisions: the husband was often a Heathen, and the wife a Christian; or, again, the husband a Christian, and the wife a Heathen. These are facts so universally known and believed, that we need not quote authorities in proof of them.

This respectable writer appears therefore not to have stated the facts which he produces under this head with sufficient ingenuousness; and he has taken care to exaggerate and improve those which he thinks useful to his purpose with all the dazzling, delusive colours of eloquence. But had the zeal of the first Christians been so intolerant as he represents it, it must have been highly unfavourable to the propagation of their religion: all their wishes to make converts would, in that case, have been counteracted by their unwillingness to mix, in the ordinary intercourse of life, with those who were to be converted. Their zeal, and the liberal spirit of their religion, were indeed secondary causes which contributed to its propagation: but their zeal was by no means so ridiculously intolerant as this writer would have us believe; if it had, it must have produced effects directly opposite to those which he ascribes to it.

22

Cause II.

In illustrating the influence of the *second* of these secondary causes to which he ascribes the propagation of Christianity, Mr Gibbon displays no less ingenuity than in tracing the nature and the effects of the first. The doctrine of a future life, improved by every additional circumstance which can give weight and efficacy to that important truth, makes a conspicuous figure in the Christian system; and it is a doctrine highly flattering to the natural hopes and wishes of the human heart.

Though the Heathen philosophers were not unacquainted with this doctrine; yet to them the spirituality of the human soul, its capacity of existence in a separate state from the body, its immortality, and its

pro-

Christia-
nity.

prospect of lasting happiness in a future life, rather appeared things possible and desirable, than truths fully established upon solid grounds. These doctrines, Mr Gibbon would persuade us, had no influence on the moral sentiments and general conduct of the Heathens. Even the philosophers, who amused themselves with displaying their eloquence and ingenuity on those splendid themes, did not allow them to influence the tenor of their lives. The great body of the people, who were occupied in pursuits very different from the speculations of philosophy, and were unacquainted with the questions discussed in the schools, were scarce ever at pains to reflect whether they consisted of a material and a spiritual part, or whether their existence was to be prolonged beyond the term of the present life; and they could not regulate their lives by principles which they did not know.

In the popular superstition of the Greeks and Romans, the doctrine of a future state was not omitted. Mankind were not only flattered with the hopes of continuing to exist beyond the term of the present life; but different conditions of existence were promised or threatened, in which retributions for their conduct in human life were to be enjoyed or suffered. Some were exalted to heaven, and associated with the gods; others were rewarded with less illustrious honours, and a more moderate state of happiness, in Elysium; and those, again, who by their conduct in life had not merited rewards, but punishments, were consigned to Tartarus. Such were the ideas of a future state which made a part of the popular superstition of the Greeks and Romans. But they produced only a very faint impression on the minds of those among whom they prevailed. They were not truths supported by evidence; they were not even plausible; they were a tissue of absurdities. They had not therefore a more powerful influence on the morals, than the more refined speculations of the philosophers.

Even the Jews, whose religion and legislature were communicated from heaven, were in general, till within a very short time before the propagation of the gospel, as imperfectly acquainted with the doctrine of a future state as the Greeks and Romans. This doctrine made no part of the law of Moses. It is but darkly and doubtfully insinuated through the other parts of the Old Testament. Those among the Jews who treated the sacred scriptures with the highest reverence, always denied that such a doctrine could be deduced from any thing which these taught; and maintained that death is the final dissolution of man.

The rude tribes who inhabited ancient Gaul, and some other nations not more civilized than they, entertained ideas of a future life, much clearer than those of the Greeks, the Romans, or the Jews.

Christianity, however, explained and inculcated the truth of this doctrine in all its splendor and all its dignity. It exhibited an alluring, yet not absurd, view of the happiness of a future life. It conferred new horrors on the place of punishment, and added new severity to the tortures to be inflicted, in another world. The authority on which it taught these doctrines, and displayed these views, was such as to silence inquiry and doubt, and to command implicit belief. What added to the influence of the doctrine of a future state of existence, thus explained and inculcated, was, that the first Christians

confidently prophesied and sincerely believed that the end of the world, the consummation of all things, was fast approaching, and that the generation then present should live to witness that awful event. Another circumstance which contributed to render the same doctrine so favourable to the propagation of Christianity was, that the first Christians dealt damnation without remorse, and almost without making any exceptions, on all who died in the belief of the absurdities of Heathen superstition. Thus taught and improved with these additional and heightening circumstances, this doctrine, partly by presenting alluring prospects and exciting pleasing hopes, partly by working upon the fears of the human heart with representations of terror, operated in the most powerful manner in extending the influence of the Christian faith.

Here, too, facts are rather exaggerated, and the inferences scarce fairly deduced. It must be confessed, that the speculations of the Heathen philosophers did not fully and undeniably establish the doctrine of the immortality of the human soul; nor can we presume to assert, in contradiction to Mr Gibbon, that their arguments could impress such a conviction of this truth as might influence in a very strong degree the moral sentiments and conduct. They must, however, have produced some influence on these. Some of the most illustrious among the Heathen philosophers appear to have been so strongly impressed with the belief of the soul's immortality, and of a future state of retribution, that their general conduct was constantly and in a high degree influenced by that belief. Plato and Socrates are eminent and well known instances. And if, in such instances as these, the belief of these truths produced such conspicuous effects; it might be fairly inferred, though we had no farther evidence, that those characters were far from being singular in this respect. It is a truth acknowledged as unquestionable in the history of the arts and sciences, that wherever any one person has cultivated these with extraordinary success, some among his contemporaries will always be found to have rivalled his excellence, and a number of them to have been engaged in the same pursuits. On this occasion we may venture, without hesitation, to reason upon the same principles. When the belief of the immortality of the human soul produced such illustrious patterns of virtue as a Plato and a Socrates; it must certainly have influenced the moral sentiments and conduct of many others,—although in an inferior degree. We speculate, we doubt, concerning the truth of many doctrines of Christianity; many who profess that they believe them, make this profession only because they have never considered seriously whether they be true or false. But, notwithstanding this, these truths still exert a powerful influence on the sentiments and manners of society in general. Thus, also, it appears, that the doctrines of ancient philosophy concerning a future life, and even the notions concerning Olympus, Elysium, and Tartarus, which made a part of the popular superstition, did produce a certain influence on the sentiments and manners of the Heathens in general. That influence was often indeed inconsiderable, and not always happy; but still it was somewhat greater than Mr Gibbon seems willing to allow. Christians have been sometimes at pains to exaggerate the absurdities of Pagan superstition, in order that the advantages

Christi-
nity.23
Observa-
tions in an-
swer.

Christianity.

Christianity.

advantages of Christianity might acquire new value from being contrasted with it. Here we find one who is rather disposed to be the enemy of Christianity, displaying, and even exaggerating, those absurdities for a very different purpose. But the truth may be safely admitted; it is only when exaggerated that it can serve any purpose inimical to the sacred authority of our holy religion. Mr Gibbon certainly represents the religious doctrine of the ancient Gauls, in respect to the immortality of the human soul and a future state, in too favourable a light. It is only because the whole system of superstition which prevailed among those barbarians is so imperfectly known, that it has been imagined to consist of more sublime doctrines than those of the popular superstition of the Greeks and Romans. The evidence which Mr Gibbon adduces in proof of what he asserts concerning these opinions of the ancient Gauls, is partial, and far from satisfactory. They *did* indeed assert and believe the soul to be immortal; but this doctrine was blended among a number of absurdities much grosser than those which characterise the popular religion of the Greeks and Romans. The latter was the superstition of a civilized people, among whom reason was unfolded and improved by cultivation, and whose manners were polished and liberal; the former was that of barbarians, among whom reason was, as it were, in its infancy, and who were strangers to the improvements of civilization. When hasty observers found that those barbarians were not absolutely strangers to the idea of immortality, they were moved to undue admiration; their surprise at finding what they had not expected, confounded their understanding, and led them to misconceive and misrepresent. What we ought to ascribe to the savage ferocity of the character of those rude tribes, has been attributed by mistake to the influence of their belief of a future state.

In the law of Moses, it must be allowed, that this doctrine is not particularly explained nor earnestly inculcated. The author of the Divine Legation of Moses, &c. has founded upon this fact an ingenious theory, which we shall elsewhere have occasion to examine. The reasons why this doctrine was not more fully explained to the Jews, we cannot pretend to assign, at least in this place; yet we cannot help thinking, that it was more generally known among the Jews than Mr Gibbon and the author of the Divine Legation are willing to allow. Though it be not strongly inculcated in their *code of laws*, yet there is some reason to think that it was known and generally prevalent among them long before the Babylonish captivity; even in different passages in the writings of Moses, it is mentioned or alluded to in an unequivocal manner. In the history of the patriarchs, it appears that this doctrine was known to *them*; it appears to have had a strong influence on the mind of Moses himself. Was David, was Solomon, a stranger to this doctrine? We cannot here descend to very minute particulars; but surely all the efforts of ingenuity must be insufficient to torture the sacred scriptures of the Old Testament, so as to prove that they contain nothing concerning the doctrine of a future state any where but in the writings of the later prophets, and that even in these it is only darkly insinuated. Were the Jews, in the earlier part of their history, so totally secluded from all intercourse with other nations, that a

doctrine of so much importance, more or less known to all around, could not be communicated to them? The Pharisees *did* admit traditions, and set upon them an undue value; yet they appear to have been considered as the most orthodox of the different sects which prevailed among the Jews: the Sadducees were rather regarded as innovators.

But though we are of opinion, that this ingenious writer allows to the doctrine of the Greek and Roman philosophers, concerning the immortality of the human soul, as well as to the notions concerning a future state, which made a part of the popular superstitions of those nations, less influence on the moral sentiments and conduct of mankind than what they really exerted; though we cannot agree with him in allowing the ideas of the immortality of the soul and of a future state, which were entertained by the Gauls and some other rude nations, to have been much superior in their nature, or much happier in their influence, than those of the Greeks and Romans; and though, in consequence of reading the Old Testament, we are disposed to think that the Jews knew somewhat more concerning the immortality of the human soul, and concerning the future state in which human beings are destined to exist, than Mr Gibbon represents them to have known: yet still we are very sensible, and very well pleased to admit, that "life and immortality were brought to light through the gospel."

The doctrine of a future life, as it was preached by the first Christians, was established on a more solid basis than that on which it had been before maintained; was freed from every absurdity; and was, in short, so much improved, that its influence, which, as it was explained by Heathen poets and philosophers, must be confessed to have been in many instances doubtful, now became favourable only to the interests of piety and virtue, and to them in a very high degree. It undoubtedly contributed to the successful propagation of Christianity; for it was calculated to attract and please both the speculating philosopher and the simple unenlightened votary of the vulgar superstition. The views which it exhibited were distinct; and all was plausible and rational, and demonstrated by the fullest evidence. But the happiness which it promised was of a less sensual nature than the enjoyments which the Heathens expected on Olympus or in Elysium; and would therefore appear less alluring to those who were not very capable of refined ideas, or preferred the gratifications of the senses in the present life to every other species of good. If the first Christians rejoiced in the hope of beholding all the votaries of Pagan idolatry afflicted with the torments of hell in a future state, and boasted of these hopes with inhuman exultation, they would in all probability rather irritate than alarm those whom they sought to convert from that superstition: the Heathens would be moved to regard with indignant scorn the preacher who pretended, that those whom they venerated as gods, heroes, and wise men, were condemned to a state of unspeakable and lasting torment. Would not every feeling of the heart revolt against the idea, that a parent, a child, a husband, a wife, a friend, a lover, or a mistress, but lately lost, and still lamented, was consigned to eternal torments for actions and opinions which they had deemed highly agreeable to superior powers?

Christiani-
ty.

We may conclude, then, with respect to the influence of this secondary cause in promoting the propagation of Christianity, that the circumstances of the Heathen world were less favourable to that influence than Mr Gibbon pretends; that the means by which he represents the primitive Christians, as improving its efficacy, were some of them not employed, and others rather likely to weaken than to strengthen it; and that therefore more is attributed to the operation of this cause than it could possibly produce.

Cause III. The *third cause*, the miraculous powers of the primitive church, is with good reason represented as having conduced very often to the conviction of infidels. Mr Gibbon's reasonings under this head are, That numerous miraculous works of the most extraordinary kind were ostentatiously performed by the first Christians: that, however, from the difficulty of fixing the period at which miraculous powers ceased to be communicated to the Christian church, and from some other circumstances, there is reason to suspect them to have been merely the pretences of imposture; but this (to use a phrase of his own) is only darkly insinuated: and, lastly, that the Heathens having been happily prepared to receive them as real by the many wonders nearly of a similar nature to which they were accustomed in their former superstition, the miracles which the first Christians employed to give a sanction to their doctrines, contributed in the most effectual manner to the propagation of Christianity.

Observa-
tions in re-
ply.

In reply to what is here advanced, it may be suggested, that the miracles recorded in the New Testament, as having been performed by the first Christians when engaged in propagating their religion, as well as a number of others recorded by the Fathers, are established as true, upon the most indubitable evidence which human testimony can afford for any fact. An ingenious Scotch writer*, who was too fond of employing his ingenuity in undermining truths generally received, has endeavoured to prove, that no human testimony, however strong and unexceptionable, can afford sufficient evidence of the reality of a miracle. But his reasonings on this head, which once excited doubt and wonder, have been since completely refuted; and mankind still continue to acknowledge, that though we are all liable to mistakes and capable of deceit, yet human testimony may afford the most convincing evidence of the most extraordinary and even supernatural facts. The reader will not expect us to enter, in this place, into a particular examination of the miracles of our Saviour, and his apostles, and the primitive church. An inquiry into these will be a capital object in another part of this work (THEOLOGY). We may here consider it as an undeniable and a generally acknowledged fact, that a certain part of those miracles were real. Such as were real, undoubtedly contributed, in a very eminent manner, to the propagation of Christianity; but they are not to be ranked among the natural and secondary causes.

It is difficult to distinguish at what period miraculous gifts ceased to be conferred on the members of the primitive church; yet we may distinguish, if we take pains to inquire with minute attention, at what period the evidence ceases to be satisfactory. We can also, by considering the circumstances of the church through the several stages of its history, form some judgment

concerning the period during which the gifts of prophesying, and speaking with tongues, and working miracles, were most necessary to Christians to enable them to assert the truth and dignity of their religion.

The Heathens were no strangers to pretended miracles and prophecies, and other seeming interpositions of superior beings, disturbing the ordinary course of nature and of human affairs: but the miracles to which they were familiarised had been so often detected to be tricks of imposture or pretences of mad enthusiasm, that, instead of being prepared to witness or to receive accounts of new miracles with easy credulity, they must have been in general disposed to view them with jealousy and suspicion. Besides, the miracles to which they had been accustomed, and those performed by the apostles and the first preachers of Christianity, were directly contradictory; and therefore the one could receive no assistance from the other.

Yet we must acknowledge, notwithstanding what we have above advanced, that as disagreements with respect to the principles and institutions of their religion very early arose among Christians; so they likewise sought to extend its influence, at a very early period, by the use of *pious frauds*. Pious frauds, too, appear to have sometimes served the immediate purposes for which they were employed, though eventually they have been highly injurious to the cause of Christianity.

We conclude, then, that Christianity was indebted to the influence of miracles in a considerable degree for its propagation: but that the real miracles of our Saviour and his apostles, &c. were not among the secondary causes of its success: that the Heathens who were to be converted were not very happily prepared for receiving the miracles of the gospel with blind credulity: that, as it is possible to discern between sufficient and insufficient evidence, so it is not more difficult to distinguish between true and false miracles: and, lastly, that false miracles were soon employed by Christians as engines to support and propagate their religion, and perhaps not unsuccessfully; but were, upon the whole, more injurious than serviceable to the cause which they were called in to maintain.

The *fourth of this series of secondary causes*, which this author thinks to have been adequate to the propagation of Christianity, is the virtues of the primitive Christians. These he is willing to attribute to other and less generous motives, rather than to the pure influence of the doctrines and precepts of their religion.

The first converts to Christianity were most of them from among the lowest and most worthless characters. The wise, the mighty, and those who were distinguished by specious virtues, were in general perfectly satisfied with their present circumstances and future prospects. People whose minds were naturally weak, unenlightened, or oppressed with the sense of atrocious guilt, and who were infamous or outcasts from society, were eager to grasp at the hopes which the gospel held out to them.

When, after enlisting under the banner of Christ, they began to consider themselves as "born again to newness of life;" remorse and fear, which easily prevail over weak minds; selfish hopes of regaining their reputation, and attaining to the honours and happiness of those mansions which Jesus was said to have gone to prepare;

Cause IV.

Christianity. prepare; with a desire to raise the honour and extend the influence of the society of which they were become members; all together operated so powerfully as to enable them to display both active and passive virtue in a very extraordinary degree. Their virtues did not flow from the purest and noblest source; yet they attracted the notice and moved the admiration of mankind. Of those who admired, some were eager to imitate; and, in order to that, thought it necessary to adopt the same principles of action.

Their virtues, too, were rather of that species which excite wonder, because uncommon, and not of essential utility in the ordinary intercourse of society; than of those which are indispensably necessary to the existence of social order, and contribute to the ease and convenience of life. Such virtues were well calculated to engage the imitation of those who had failed egregiously in the practice of the more social virtues.

Thus they practised extraordinary, but useless and unsocial, virtues, upon no very generous motives; and those virtues drew upon them the eyes of the world, and induced numbers to embrace their faith.

Observations, in answer. We must, however unwillingly, declare, that this is plainly an uncandid account of the virtues of the primitive Christians, and the motives from which they originated. The social virtues are strongly recommended through the gospel. No degree of mortification or self-denial, or seclusion from the ordinary business and amusements of social life, was required of the early converts to Christianity; save what was indispensably necessary to wean them from the irregular habits in which they had before indulged, and which had rendered them nuisances in society, and to form them to new habits equally necessary to their happiness and their usefulness in life. We allow that they practised virtues which in other circumstances would, however splendid, have been unnecessary. But in the difficult circumstances in which the first Christians were placed, the virtues which they practised were in the highest degree social. The most prominent feature in their character was, "their continuing to entertain sentiments of generous benevolence, and to discharge scrupulously all the social duties," towards those who exercised neither charity nor humanity, and frequently not even bare integrity and justice, in their conduct towards them.

It cannot be said with truth, that such a proportion of the primitive Christians were people whose characters had been infamous and their circumstances desperate, as that the character of the religion which they embraced can suffer from this circumstance. Nor were they *only* the weak and illiterate whom the apostles and their immediate successors converted by their preaching. The criminal, to be sure, rejoiced to hear that he might obtain absolution of his crimes; the mourner was willing to receive comfort; minds of refined and generous feelings were deeply affected with that goodness which had induced the Son of God to submit to the punishment due to sinners: but the simplicity, the rationality, and the beauty of the Christian system, likewise prevailed in numerous instances over the pride and prejudices of the great and the wise; in so many instances, as are sufficient to vindicate the Christian church from the aspersions by which it has been represented, as being in the first period of its existence merely a body of *criminals and idiots*.

Christianity. The principles, too, from which the virtues of the first Christians originated, were not peculiarly mean and selfish; nay, they seem to have been uncommonly sublime and disinterested. Remorse in the guilty mind is a natural and reasonable sentiment; the desire of happiness in every human breast is equally so. It is uncandid to cavil against the first Christians for being, like the rest of mankind, influenced by these sentiments: And when we behold them overlooking temporary possessions and enjoyments, extending their views to futurity, and "living by faith;" when we observe them "doing good to those who hated them, blessing those who cursed them, and praying for those by whom they were despitefully used;" can we deny their virtues to have been of the most generous and disinterested kind?

We allow, then, that the virtues of the first Christians must have contributed to the propagation of their religion: but it is with pain that we observe this respectable writer studiously labouring to misrepresent the principles from which those virtues arose; and not only the principles from which they arose, but also their importance in society.

The *fifth cause* was the mode of church government adopted by the first Christians, by which they were knit together in one society; who preferred the church and its interests to their country and civil concerns. *Cause V. with observations.* We wish not to deny, that the mutual attachment of the primitive Christians contributed to spread the influence of their religion; and the order, which they maintained, in consequence of being animated with this spirit of brotherly love, and with such ardent zeal for the glory of God, must no doubt have produced no less happy effects among them than order and regularity produce on every other occasion on which they are strictly observed. But whether the form of church-government, which was gradually established in the Christian church, was actually the happiest that could possibly have been adopted; or whether, by establishing a distinct society, with separate interests, within the Roman empire, it contributed to the dissolution of that mighty fabric, we cannot here pretend to inquire. These are subjects of discussion, with respect to which we may with more propriety endeavour to satisfy our readers elsewhere.

From the whole of this review of what Mr Gibbon has so speciously advanced concerning the influence of these five secondary causes in the propagation of the gospel, we think ourselves warranted to conclude, *conclusion concerning the influence of the five causes.* That the zeal of the first Christians was not, as he represents it, intolerant: That the doctrine of the immortality of the human soul was somewhat better understood in the heathen world, particularly among the Greeks and Romans and the Jews, than he represents it to have been; and had an influence somewhat happier than what he ascribes to it: That the additional circumstances by which, he tells us, the first preachers of Christianity improved the effects of this doctrine, were far from being calculated to allure converts: That the heathens, therefore, were not quite so well prepared for an eager reception of this doctrine as he would persuade us they were; and, of consequence, could not be influenced by it in so considerable a degree, in their conversion: That real, unquestionable miracles, performed by our Saviour, by his apostles, and

Christiani-
ty,
Christians.

by their successors, *did* contribute signally to the propagation of Christianity; but are not to be ranked among the secondary causes: That weakness and blind zeal did at times employ pretended miracles for the same purpose not altogether ineffectually: That though these despicable and wicked means might be in some instances successful; yet they were, upon the whole, much more injurious than beneficial: That the virtues of the primitive Christians arose from the most generous and noble motives, and were in their nature and tendency highly favourable to social order, and to the comfort of mankind in the social state: And, lastly, That the order and regularity of church-government, which were gradually established among the first Christians, contributed greatly to maintain the dignity and spread the influence of their religion; but do not appear to have disjoined them from their fellow-subjects or to have rendered them inimical to the welfare of the state of which they were members.

Upon the whole, then, we do not see that these secondary causes were equal to the effects that have been ascribed to them; and it seems undeniable, that others of a superior kind co-operated with them. We earnestly recommend to the perusal of the reader a valuable performance of Lord Hailes's, in which he enquires into Mr Gibbon's assertions and reasonings, concerning the influence of these five causes, with the utmost accuracy of information, strength and clearness of reasoning, and elegant simplicity of style, and without virulence or passion.

CHRISTIANS, those who profess the religion of Christ: See CHRISTIANITY and MESSIAH.—The name *Christian* was first given at Antioch in the year 42 to such as believed in Christ, as we read in the Acts: till that time they were called *disciples*.

The first Christians distinguished themselves in the most remarkable manner by their conduct and their virtues. The faithful, whom the preaching of St Peter had converted, hearkened attentively to the exhortations of the Apostles, who failed not carefully to instruct them, as persons who were entering upon an entirely new life. They went every day to the temple with one heart and one mind, and continued in prayers; doing nothing different from the other Jews, because it was yet not time to separate from them. But they made a still greater progress in virtue; for they sold all that they possessed, and distributed their goods in proportion to the wants of their brethren. They *eat their meat with gladness and singleness of heart, praising God, and having favour with all the people*. St Chrysostom, examining from what source the eminent virtue of the first Christians flowed, ascribes it principally to their divesting themselves of their possessions: "For (says that father) persons from whom all that they have is taken away, are not subject to sin: whereas, whoever has large possessions, wants not a devil or a tempter to draw him into hell by a thousand ways."

The Jews were the first and the most inveterate enemies the Christians had. They put them to death as often as they had it in their power: and when they revolted against the Romans in the time of the emperor Adrian, Barchochebas, the head of that revolt, employed against the Christians the most rigorous punishments to compel them to blaspheme and renounce Jesus Christ. And we find that, even in the third century, they endeavoured to get into their

hands Christian women, in order to scourge and stone them in their synagogues. They cursed the Christians solemnly three times a-day in their synagogues, and their rabbins would not suffer them to converse with Christians upon any occasion. Nor were they contented to hate and detest them; but they dispatched emissaries all over the world to defame the Christians, and spread all sorts of calumnies against them. They accused them, among other things, of worshipping the sun and the head of an ass. They reproached them with idleness, and being an useless race of people. They charged them with treason, and endeavouring to erect a new monarchy against that of the Romans. They affirmed, that, in celebrating their mysteries, they used to kill a child and eat its flesh. They accused them of the most shocking incests, and of intemperance in their feasts of charity. But the lives and behaviour of the first Christians were sufficient to refute all that was said against them, and evidently demonstrated that these accusations were mere calumny and the effect of inveterate malice.

Pliny the younger, who was governor of Pontus and Bithynia between the years 103 and 105, gives a very particular account of the Christians in that province, in a letter which he wrote to the emperor Trajan, of which the following is an extract: "I take the liberty, Sir, to give you an account of every difficulty which arises to me. I have never been present at the examination of the Christians; for which reason I know not what questions have been put to them, nor in what manner they have been punished. My behaviour towards those who have been accused to me has been this: I have interrogated them, in order to know whether they were really Christians. When they have confessed it, I have repeated the same question two or three times, threatening them with death if they did not renounce this religion. Those who have persisted in their confession, have been, by my order, led to punishment. I have even met with some Roman citizens guilty of this phrensy, whom, in regard to their quality, I have set apart from the rest, in order to send them to Rome. These persons declare, that their whole crime, if they are guilty, consists in this; that, on certain days, they assemble before sun-rise, to sing alternately the praises of Christ, as of a God, and to oblige themselves, by the performance of their religious rites, not to be guilty of theft, or adultery, to observe inviolably their word, and to be true to their trust. This deposition has obliged me to endeavour to inform myself still farther of this matter, by putting to the torture two of their women-servants, whom they call *deaconesses*: but I could learn nothing more from them, than that the superstition of these people is as ridiculous as their attachment to it is astonishing."

There is extant a justification, or rather panegyric, of the Christians, pronounced by the mouth of a Pagan prince. It is a letter of the emperor Antoninus, written in the year 152, in answer to the States of Asia, who had accused the Christians of being the cause of some earthquakes which had happened in that part of the world. The emperor advises them to "take care, lest, in torturing and punishing those whom they accused of Atheism (meaning the Christians),

Christians. stians), they should render them more obstinate, instead of prevailing upon them to change their opinion; since their religion taught them to suffer with pleasure for the sake of God." As to the earthquakes which had happened, he puts them in mind, "that they themselves are always discouraged, and sink under such misfortunes; whereas the Christians never discovered more cheerfulness and confidence in God than upon such occasions." He tells them, that "they pay no regard to religion, and neglect the worship of the Eternal; and, because the Christians honour and adore Him, therefore they are jealous of them, and persecute them even to death." He concludes: "Many of the governors of provinces have formerly written to my father concerning them; and his answer always was, that they should not be molested or disturbed, provided they quietly submitted to the authority of the government. Many persons have likewise consulted me upon this affair, and I have returned the same answer to them all; namely, that if any one accuses a Christian merely on account of his religion, the accused person shall be acquitted, and the accuser himself punished." This ordinance, according to Eusebius, was publicly fixed up at Ephesus in an assembly of the states.

It is no difficult matter to discover the causes of the many persecutions to which the Christians were exposed during the three first centuries. The purity of the Christian morality, directly opposite to the corruption of the Pagans, was doubtless one of the most powerful motives of the public aversion. To this may be added, the many calumnies unjustly spread about concerning them by their enemies, particularly the Jews. And this occasioned so strong a prejudice against them, that the Pagans condemned them without inquiring into their doctrine, or permitting them to defend themselves. Besides, their worshipping Jesus Christ, as God, was contrary to one of the most ancient laws of the Roman empire, which expressly forbade the acknowledging of any God which had not been approved by the senate.

But notwithstanding the violent opposition made to the establishment of the Christian religion, it gained ground daily, and very soon made a surprising progress in the Roman empire. In the third century, there were Christians in the camp, in the senate, in the palace; in short every where, but in the temples and the theatres: they filled the towns, the country, the islands. Men and women, of all ages and conditions, and even those of the first dignities, embraced the faith; insomuch that the Pagans complained that the revenues of their temples were ruined. They were in such great numbers in the empire, that (as Tertulian expresses it) were they to have retired into another country, they would have left the Romans only a frightful solitude.

The primitive Christians were not only remarkable for the practice of every virtue; they were also very eminently distinguished by the many miraculous gifts and graces bestowed by God upon them. "Some of the Christians (says Irenæus) drive out devils, not in appearance only, but so as that they never return; whence it often happens, that those who are dispossessed of evil spirits embrace the faith and are received into the church. Others know what is to come, see visions, and deliver oracles as prophets. Others heal

the sick by laying their hands on them, and restore them to perfect health: and we find some who even raise the dead.—It is impossible to reckon up the gifts and graces which the church has received from God—what they have freely received they as freely bestow. They obtain these gifts by prayer alone, and invocation of the name of Jesus Christ, without any mixture of enchantment or superstition."

We shall here subjoin the remarkable story, attested by Pagan authors themselves, concerning the *Christian Legion* in the army of the emperor Marcus Aurelius. That prince having led his forces against the Quadi, a people on the other side of the Danube, was surrounded and hemmed in by the enemy in a disadvantageous place, and where they could find no water. The Romans were greatly embarrassed, and, being pressed by the enemy, were obliged to continue under arms, exposed to the violent heat of the sun, and almost dead with thirst; when, on a sudden, the clouds gathered, and the rain fell in great abundance. The soldiers received the water in their bucklers and helmets, and satisfied both their own thirst and that of their horses. The enemy, presently after, attacked them; and so great was the advantage they had over them, that the Romans must have been overthrown, had not heaven again interposed by a violent storm of hail, mixed with lightning, which fell on the enemy, and obliged them to retreat. It was found afterwards, that one of the legions, which consisted of Christians, had by their prayers, which they offered up on their knees before the battle, obtained this favour from heaven: and from this event that legion was surnamed *The thundering Legion*. See, however, the criticism of Mr Moyle on this story in his *Works*, vol. ii. p. 81—390. See also *Mosheim's Church History*, vol. i. p. 124.

Such were the primitive Christians, whose religion has by degrees spread itself over all parts of the world, though not with equal purity in all. And though, by the providence of God, Mahometans and Idolaters have been suffered to possess themselves of those places in Greece, Asia, and Africa, where the Christian religion formerly most flourished; yet there are still such remains of the Christian religion among them as to give them opportunity sufficient to be converted. For, in the dominions of the Turk in Europe, the Christians make two third parts at least of the inhabitants; and in Constantinople itself there are above twenty Christian churches, and above thirty in Thessalonica. Philadelphia, now called *Ala-shahir*, has no fewer than twelve Christian churches. The whole island of Chio is governed by Christians; and some islands of the Archipelago are inhabited by Christians only. In Africa, besides the Christians living in Egypt, and in the kingdom of Congo and Angola, the islands upon the western coasts are inhabited by Christians; and the vast kingdom of Abyssinia, supposed to be as big as Germany, France, Spain, and Italy, put together, is possessed by Christians. In Asia, most part of the empire of Russia, the countries of Circassia and Mingrelia, Georgia, and Mount Libanus, are inhabited only by Christians. In America, it is notorious that the Christians are very numerous, and spread over most parts of that vast continent.

CHRISTIANS of St John, a sect of Christians very numerous in Balsara and the neighbouring towns: they formerly

Christians
||
Christina.

formerly inhabited along the river Jordan, where St John baptized, and it was from thence they had their name. They hold an anniversary feast of five days; during which they all go to the bishop, who baptizes them with the baptism of St John. Their baptism is also performed in rivers, and that only on Sundays: they have no notion of the third Person in the Trinity; nor have they any canonical book, but abundance full of charms, &c. Their bishoprics descend by inheritance, as our estates do, though they have the ceremony of an election.

CHRISTIANS of St Thomas, a sort of Christians in a peninsula of India on this side of the Gulf: they inhabit chiefly at Cranganor, and the neighbouring country: these admit of no images; and receive only the cross, to which they pay a great veneration: they affirm, that the souls of the saints do not see God till after the day of judgment: they acknowledge but three sacraments, *viz.* baptism, orders, and the eucharist: they make no use of holy oils in the administration of baptism; but, after the ceremony, anoint the infant with an unction composed of oil and walnuts, without any benediction. In the eucharist, they consecrate with little cakes made of oil and salt, and instead of wine make use of water in which raisins have been infused.

CHRISTIANA, a town of Norway, in the province of Aggerhuys, situated on a bay of the sea. E. Long. 10. 15. N. Lat. 59. 30.

CHRISTIANOPLE, a port-town of Sweden, situated on the Baltic Sea, in the territory of Blecking, and province of South Gothland. E. Long. 15. 40. N. Lat. 57°.

CHRISTIANSTADT, a strong fortified town of Sweden; situated in the territory of Blecking and province of South Gothland. It was built in 1614 by Christian IV. king of Denmark, when this province belonged to the Danes; and finally ceded to the Swedes by the peace of Roskild in 1658. The town is small but neatly built, and is esteemed the strongest fortress in Sweden. The houses are all of brick, and mostly stuccoed white. It stands in a marshy plain close to the river Helge-a, which flows into the Baltic at Ahus, about the distance of 20 miles, and is navigable only for small craft of seven tons burden. English vessels annually resort to this port for alum, pitch, and tar. The inhabitants have manufactures of cloth and filken stuffs, and carry on a small degree of commerce. E. Long. 14. 40. N. Lat. 56. 30.

CHRISTINA, daughter of Gustavus Adolphus king of Sweden, was born in 1626; and succeeded to the crown in 1633, when only seven years of age. This princess discovered even in her infancy, what she afterwards expressed in her memoirs, an invincible antipathy for the employments and conversation of women; and she had the natural awkwardness of a man with respect to all the little works which generally fall to their share. She was, on the contrary, fond of violent exercises, and such amusements as consist in feats of strength and activity. She had also both ability and taste for abstracted speculations; and amused herself with language and the sciences, particularly that of legislature and government. She derived her knowledge of ancient history from its source; and Polybius and Thucydides were her favourite authors. As she was

the sovereign of a powerful kingdom, it is not strange that almost all the princes in Europe aspired to her bed. Among others, were the Prince of Denmark, the Elector Palatine, the Elector of Brandenburg, the King of Spain, the King of the Romans, Don John of Austria; Sigismund of Rockocci, count and general of Castovia; Stanislaus king of Poland; John Cassimir his brother; and Charles Gustavus duke of Deuxs Ponts, of the Bavarian Palatinate family, son of her father the great Gustavus's sister, and consequently her first cousin. To this nobleman, as well as to all his competitors, she constantly refused her hand; but she caused him to be appointed her successor by the states. Political interests, differences of religion, and contrariety of manners, furnished Christina with pretences for rejecting all her suitors; but her true motives were the love of independence, and a strong aversion she had conceived, even in her infancy, from the marriage yoke. "Do not force me to marry (said she to the states); for if I should have a son, it is not more probable that he should be an Augustus than a Nero."

An accident happened in the beginning of her reign which gave her a remarkable opportunity of displaying the strength and equanimity of her mind. As she was at the chapel of the castle of Stockholm, assisting at divine service with the principal lords of her court, a poor wretch, who was disordered in his mind, came to the place with a design to assassinate her. This man, who was preceptor of the college, and in the full vigour of his age, chose, for the execution of his design, the moment in which the assembly was performing what in the Swedish church is called an *act of recollection*; a silent and separate act of devotion, performed by each individual kneeling and hiding the face with the hand. Taking this opportunity, he rushed through the crowd, and mounted a ballustrade within which the queen was upon her knees. The Baron Braki, chief justice of Sweden, was alarmed, and cried out; and the guards crossed their partisans, to prevent his coming further: but he struck them furiously on one side; leaped over the barrier; and, being then close to the queen, made a blow at her with a knife which he had concealed without a sheath in his sleeve. The queen avoided the blow, and pushed the captain of her guards, who instantly threw himself upon the assassin, and seized him by the hair. All this happened in less than a moment of time. The man was known to be mad, and therefore nobody supposed he had any accomplices: they therefore contented themselves with locking him up; and the queen returned to her devotion without the least emotion that could be perceived by the people, who were much more frightened than herself.

One of the great affairs that employed Christina while she was upon the throne, was the peace of Westphalia, in which many clashing interests were to be reconciled, and many claims to be ascertained. It was concluded in the month of October 1648. The success of the Swedish arms rendered Christina the arbitress of this treaty; at least as to the affairs of Sweden, to which this peace confirmed the possession of many important countries. No public event of importance took place during the rest of Christina's reign; for there were neither wars abroad, nor troubles at home. This quiet might be the effect of chance; but it might also be the effect of a good administration,

Christina.

Christina. ministration, and the great reputation of the queen; and the love her people had for her ought to lead us to this determination. Her reign was that of learning and genius. She drew about her, wherever she was, all the distinguished characters of her time: Grotius, Pascal, Bochart, Descartes, Gassendi, Saumaise, Naude, Vossius, Heinsius, Meibom, Scudery, Menage, Lucas, Holstenius, Lambecius, Bayle, madam Dacier, Filicaia, and many others. The arts never fail to immortalize the prince who protects them; and almost all these illustrious persons have celebrated Christina, either in poems, letters, or literary productions of some other kind, the greater part of which are now forgotten. They form, however, a general cry of praise, and a mass of testimonials which may be considered as a solid basis of reputation. Christina, however, may be justly reproached with want of taste, in not properly assigning the rank of all these persons, whose merits, though acknowledged, were yet unequal; particularly for not having been sufficiently sensible of the superiority of Descartes, whom she disgusted, and at last wholly neglected. The rapid fortune which the adventurer Michon, known by the name of *Bourdelot*, acquired by her countenance and liberality, was also a great scandal to literature. He had no pretensions to learning; and though sprightly, was yet indecent. He was brought to court by the learned Saumaise; and, for a time, drove literary merit entirely out of it, making learning the object of his ridicule, and exacting from Christina an exorbitant tribute to the weakness and inconstancy of her sex; for even Christina, with respect to this man, showed herself to be weak and inconstant. At last she was compelled, by the public indignation, to banish this unworthy minion; and he was no sooner gone, than her regard for him was at an end. She was ashamed of the favour she had shown him; and, in a short time, thought of him with hatred or contempt. This Bourdelot, during his ascendancy over the queen, had supplanted count Magnus de la Gardie, son of the constable of Sweden, who was a relation, a favourite, and perhaps the lover of Christina. M. de Motteville, who had seen him ambassador in France, says, in his memoirs, that he spoke of his queen in terms so passionate and respectful, that every one concluded his attachment to her to be more ardent and tender, than a mere sense of duty can produce. This nobleman fell into disgrace because he showed an inclination to govern; while M. Bourdelot seemed to aim at nothing more than to amuse; and concealed, under the unsuspected character of a droll, the real ascendancy which he exercised over the queen's mind.

About this time, an accident happened to Christina which brought her into still greater danger than that which has been related already. Having given orders for some ships of war to be built at the port of Stockholm, she went to see them when they were finished; and as she was going on board of them, cross a narrow plank, with admiral Fleming, his foot slipping, he fell, and drew the queen with him into the sea, which in that place was near 90 feet deep. Anthony Steinberg, the queen's first equerry, instantly threw himself into the water, laid hold of her robe, and, with such assistance as was given him, got the queen ashore:

Christina. during this accident, her recollection was such, that the moment her lips were above water, she cried, out, "Take care of the Admiral." When she was got out of the water, she discovered no emotion either by her gesture or countenance; and she dined the same day in public, where she gave a humorous account of her adventure.

But, though at first she was fond of the power and splendor of royalty, yet she began at length to feel that it embarrassed her; and the same love of independence and liberty which had determined her against marriage, at last made her weary of her crown. As, after her first disgust, it grew more and more irksome to her, she resolved to abdicate; and, in 1652, communicated her resolution to the senate. The senate zealously remonstrated against it; and was joined by the people; and even by Charles Gustavus himself, who was to succeed her: she yielded to their importunities, and continued to sacrifice her own pleasure to the will of the public till the year 1654, and then she carried her design into execution. It appears by one of her letters to M. Canut, in whom she put great confidence, that she had meditated this project for more than eight years; and that she had communicated it to him five years before it took place.

The ceremony of her abdication was a mournful solemnity, a mixture of pomp and sadness, in which scarce any eyes but her own were dry. She continued firm and composed through the whole; and, as soon as it was over, prepared to remove into a country more favourable to science than Sweden was. Concerning the merit of this action, the world has always been divided in opinion; it has been condemned alike both by the ignorant and the learned, the trifler and the sage. It was admired, however, by the great Conde: "How great was the magnanimity of this princess (said he), who could so easily give up that for which the rest of mankind are continually destroying each other, and which so many throughout their whole lives pursue without attaining!" It appears, by the works of St Evermond, that the abdication of Christina was at that time the universal topic of speculation and debate in France. Christina, besides abdicating her crown, abjured her religion; but this act was universally approved by one party and censured by another; the Papists triumphed, and the Protestants were offended. No prince, after a long imprisonment, ever showed so much joy upon being restored to his kingdom, as Christina did in quitting hers. When she came to a little brook, which separates Sweden from Denmark, she got out of her carriage; and leaping to the other side, cried out in a transport of joy, "At last I am free, and out of Sweden, whither, I hope, I shall never return." She dismissed her women, and laid by the habit of her sex: "I would become a man (said she); yet I do not love men because they are men, but because they are not women." She made her abjuration at Brussels; where she saw the great Conde, who, after his defection, made that city his asylum. "Cousin (said she), who would have thought, ten years ago, that we should have met at this distance from our countries?"

The inconstancy of Christina's temper appeared in her going continually from place to place: from Brussels

Christina. fels she went to Rome; from Rome to France, and from France she returned to Rome again; after this she went to Sweden, where she was not very well received; from Sweden she went to Hamburgh, where she continued a year, and then went again to Rome; from Rome she returned to Hamburgh; and again to Sweden, where she was still worse received than before; upon which she went back to Hamburgh, and from Hamburgh again to Rome. She intended another journey to Sweden; but it did not take place, any more than an expedition to England, where Cromwell did not seem well disposed to receive her; and after many wanderings, and many purposes of wandering still more, she at last died at Rome in 1689.

It must be acknowledged, that her journeys to Sweden had a motive of necessity; for her appointments were very ill paid, though the states often confirmed them after her abdication: but to other places she was led merely by a roving disposition; and, what is more to her discredit, she always disturbed the quiet of every place she came into, by exacting greater deference to her rank as queen than she had a right to expect, by her total non-conformity to the customs of the place, and by continually exciting and fomenting intrigues of state. She was indeed always too busy, even when she was upon the throne; for there was no event in Europe in which she was not ambitious of acting a principal part. During the troubles in France by the faction called the *Fronde*, she wrote with great eagerness to all the interested parties, officiously offering her mediation to reconcile their interests, and calm their passions, the secret springs of which it was impossible she should know. This was first thought a dangerous, and afterwards a ridiculous, behaviour. During her residence in France she gave universal disgust, not only by violating all the customs of the country, but by practising others directly opposite. She treated the ladies of the court with the greatest rudeness and contempt: when they came to embrace her, she, being in man's habit, cried out, "What a strange eagerness have these women to kiss me! is it because I look like a man?"

But though she ridiculed the manners of the French court, she was very solicitous to enter into its intrigues. Louis XIV. then very young, was enamoured of Mademoiselle de Mancini niece to cardinal Mazarine; Christina flattered their passion, and offered her service. "I would fain be your confidant (said she); if you love, you must marry."

The murder of Monaldeschi is, to this hour, an inscrutable mystery. It is, however, of a piece with the expressions constantly used by Christina in her letters, with respect to those with whom she was offended; for she scarce ever signified her displeasure without threatening the life of the offender. "If you fail in your duty, (said she to her secretary, whom she sent to Stockholm after her abdication), not all the power of the king of Sweden shall save your life, though you should take shelter in his arms." A musician having quitted her service for that of the duke of Savoy, she was so transported with rage as to disgrace herself by these words, in a letter written with her own hand: "He lives only for me; and if he does not sing for me, he shall not sing long for any body."

N^o. 79.

Bayle was also threatened for having said that the letter which Christina wrote, upon the revocation of the edict of Nantes, was "a remain of Protestantism;" but he made his peace by apologies and submission. See the article *BAYLE*.

Upon the whole, she appears to have been an uncommon mixture of faults and great qualities; which, however it might excite fear and respect, was by no means amiable. She had wit, taste, parts, and learning: she was indefatigable upon the throne; great in private life; firm in misfortunes; impatient of contradiction; and, except in her love of letters, inconstant in her inclinations. The most remarkable instance of this fickleness is, That after she had abdicated the crown of Sweden, she intrigued for that of Poland. She was, in every action and pursuit, violent and ardent in the highest degree; impetuous in her desires, dreadful in her resentment, and fickle in her conduct.

She says of herself, that "she was mistrustful, ambitious, passionate, haughty, impatient, contemptuous, satirical, incredulous, undevout, of an ardent and violent temper, and extremely amorous;" a disposition, however, to which, if she may be believed, her pride and her virtue were always superior. In general, her failings were those of her sex, and her virtues the virtues of ours.

Santa-CHRISTINA, one of the *MARQUESAS Islands*.

CHRISTMAS-DAY, a festival of the Christian church; observed on the 25th of December, in memory of the *nativity* or birth of Jesus Christ. As to the antiquity of this festival, the first footsteps we find of it are in the second century, about the time of the emperor Commodus. The decretal epistles indeed carry it up a little higher; and say that Telesphorus, who lived in the reign of Antonius Pius, ordered divine service to be celebrated, and an angelical hymn to be sung, the night before the nativity of our Saviour. However, that it was kept before the times of Constantine we have a melancholy proof: for whilst the persecution raged under Dioclesian, who then kept his court at Nicomedia, that prince, among other acts of cruelty, finding multitudes of Christians assembled together to celebrate Christ's nativity, commanded the church-doors where they were met to be shut, and fire to be put to it, which, in a short time, reduced them and the church to ashes.

CHRISTOPHER'S, St. one of the Caribbee islands, in America, lying to the north-west of Nevis, and about 60 miles west of Antigua. It was formerly inhabited by the French and English; but, in 1713, it was ceded entirely to the latter. In 1782, it was taken by the French, but restored to Britain at the peace. It is about 20 miles in breadth, and seven in length; and has high mountains in the middle, whence rivules run down. Between the mountains are dreadful rocks, horrid precipices, and thick woods; and in the south-west part of the island, hot sulphureous springs at the foot of them. The air is good; the soil light, sandy, and fruitful; but the island is subject to hurricanes. The produce is chiefly sugar, cotton, ginger, indigo, and the tropical fruits. W. Long. 62. 32. N. Lat. 17. 30.

CHROASTACES, in natural history, a genus of pellucid gems, comprehending all those of variable colours, as viewed in different lights; of which kinds are

Christina
||
Chroastaces.

Chromatic are the *opal* and the *asteria* or *oculus cati*. See *OPAL*, and *ASTERIA*.

CHROMATIC, a kind of music which proceeds by several semitones in succession. The word is derived from the Greek *χρῶμα*, which signifies *colour*. For this denomination several causes are assigned, of which none appear certain, and all equally unsatisfactory. Instead, therefore, of fixing upon any, we shall offer a conjecture of our own; which, however, we do not impose upon the reader as more worthy of his attention than any of the former. *χρῶμα* may perhaps not only signify a *colour*, but that shade of a colour by which it melts into another, or what the French call *nuance*. If this interpretation be admitted, it will be highly applicable to semitones; which being the smallest interval allowed in the diatonic scale, will most easily run one into another. To find the reasons assigned by the ancients for this denomination, and their various divisions of the chromatic species, the reader may have recourse to the same article in Rousseau's Musical Dictionary. At present, that species consists in giving such a procedure to the fundamental bass, that the parts in the harmony, or at least some of them, may proceed by semitones, as well in rising as descending; which is most frequently found in the minor mode, from the alterations to which the sixth and seventh note are subjected, by the nature of the mode itself.

The successive semitones used in the *chromatic* species are rarely of the same kind; but alternatively major and minor, that is to say, *chromatic* and *diatonic*: for the interval of a minor tone contains a minor or chromatic semitone, and another which is major or diatonic; a measure which temperament renders common to all tones: so that we cannot proceed by two minor semitones which are conjunctive in succession, without entering into the enharmonic species; but two major semitones twice follow each other in the *chromatic* order of the scale.

The most certain procedure of the fundamental bass *Chromatic* to generate the chromatic elements in ascent, is alternately to descend by thirds, and rise by fourths, whilst all the chords carry the third major. If the fundamental bass proceeds from dominant to dominant by perfect cadences avoided, it produces the *chromatic* in descending. To produce both at once, you interweave the perfect and broken cadences, but at the same time avoid them.

As at every note in the *chromatic* species one must change the tone, that succession ought to be regulated and limited for fear of deviation. For this purpose, it will be proper to recollect, that the space most suitable to *chromatic* movements, is between the extremes of the dominant and the tonic in ascending, and between the tonic and the dominant in descending. In the major mode, one may also chromatically descend from the dominant upon the second note. This transition is very common in Italy; and, notwithstanding its beauty, begins to be a little too common amongst us.

The chromatic species is admirably fitted to express grief and affliction: these sounds boldly struck in ascending tear the soul. Their power is no less magical in descending; it is then that the ear seems to be pierced with real groans. Attended with its proper harmony, this species appears proper to express every thing: but its completion, by concealing the melody, sacrifices a part of its expression; and for this disadvantage, arising from the fullness of the harmony, it can only be compensated by the nature and genius of the movement. We may add, that in proportion to the energy of this species, the composer ought to use it with greater caution and parsimony. Like those delicate viands, which when profusely administered, immediately surfeit us with their abundance: as much as they delight us when enjoyed with temperance, so much do they disgust when devoured with prodigality.

CHROMATIC, *Enharmonic*. See **ENHARMONIC**.

C H R O M A T I C S;

THAT part of optics which explains the several properties of the colours of light, and of natural bodies.

¹
Different
hypotheses
concerning
colours.

Before the time of Sir Isaac Newton, we find no hypothesis concerning colours of any consequence. The opinions of the old philosophers, however, we shall briefly mention, in order to gratify the curiosity of our readers. The Pythagoreans called colour the superficies of body. Plato said that it was a flame issuing from them. According to Zeno, it is the first configuration of matter; and Aristotle said it was that which moved bodies actually transparent. Descartes asserted, that colour is a modification of light; but he imagined, that the difference of colour proceeds from the prevalence of the direct or rotatory motion of the particles of light. Father Grimaldi, Dechales, and many others, thought the differences of colour depended upon the quick or slow vibrations of a certain elastic medium filling the whole universe. Rohault imagined, that the different colours were made by the rays of light entering the eye at different angles with

VOL. IV. Part II.

respect to the optic axis; and from the phenomenon of the rainbow, he pretended to calculate the precise quantity of the angle that constituted each particular colour. Lastly, Dr Hooke, the rival of Newton, imagined that colour is caused by the sensation of the oblique or uneven pulse of light; and this being capable of no more than two varieties, he concluded there could be no more than two primary colours.

In the year 1666, Sir Isaac Newton began to investigate this subject; and finding the coloured image of the sun, formed by a glass prism, to be of an oblong, and not of a circular form, as, according to the laws of refraction, it ought to be, he began to conjecture that light is not *homogeneous*; but that it consists of rays, some of which are much more refrangible than others. See this discovery fully explained and ascertained under the article **OPTICS**.

This method of accounting for the different colours of bodies, from their reflecting this or that kind of rays most copiously, is so easy and natural, that Sir Isaac's system quickly overcame all objections, and to

²
This subject
investigated
by Sir Isaac
Newton.

this day continues to be almost universally believed. It is now acknowledged, that the light of the sun, which to us seems perfectly homogeneous and white, is composed of no fewer than seven different colours, viz. red, orange, yellow, green, blue, purple, and violet or indigo. A body which appears of a red colour, hath the property of reflecting the red rays more powerfully than any of the others; and so of the orange, yellow, green, &c. A body which is of a black colour, instead of reflecting, *absorbs* all or the greatest part of the rays that fall upon it; and, on the contrary, a body which appears white, reflects the greatest part of the rays indiscriminately, without separating the one from the other.

The foundation of a rational theory of colours being thus laid, it next became natural to inquire, by what peculiar mechanism in the structure of each particular body it was fitted to reflect one kind of rays more than another? This Sir Isaac Newton attributes to the density of these bodies. Dr Hooke had remarked, that thin transparent substances, particularly water and soap blown into bubbles, exhibited various colours according to their thinness; though, when they have a considerable degree of thickness, they appear colourless; and Sir Isaac himself had observed, that as he was compressing two prisms hard together, in order to make their sides (which happened to be a little convex) to touch one another, in the place of contact they were both perfectly transparent, as if they had been

3
Colours appearing between two glass plates.

but one continued piece of glass. Round the point of contact, where the glasses were a little separated from each other, rings of different colours appeared. To observe more nicely the order of the colours produced in this manner, he took two object-glasses; one of them a plano-convex one belonging to a 14 feet refracting telescope, and the other a large double convex one for a telescope of about 50 feet; and laying the former of them upon the latter, with its plain side downwards, he pressed them slowly together; by which means the colours very soon emerged, and appeared distinct to a considerable distance. Next to the pellucid central spot, made by the contact of the glasses, succeeded blue, white, yellow, and red. The blue was very little in quantity, nor could he discern any violet in it; but the yellow and red were very copious, extending about as far as the white, and four or five times as far as the blue. The next circuit immediately surrounding these, consisted of violet, blue, green, yellow, and red: all these were copious and vivid, except the green, which was very little in quantity, and seemed more faint and dilute than the other colours. Of the other four, the violet was the least in extent; and the blue less than the yellow or red. The third circle of colours was purple, blue, green, yellow, and red. In this the purple seemed more reddish than the violet in the former circuit, and the green was more conspicuous; being as brisk and copious as any of the other colours, except the yellow; but the red began to be a little faded, inclining much to purple. The fourth circle consisted of green and red; and of these the green was very copious and lively, inclining on the one side to blue, and on the other to yellow; but in this fourth circle there was neither violet, blue, nor yellow, and the red was very imperfect and dirty.

All the succeeding colours grew more and more imperfect and dilute, till after three or four revolutions they ended in perfect whiteness.

As the colours were thus found to vary according to the different distances of the glass-plates from each other, our author thought that they proceeded from the different thickness of the plate of air intercepted between the glasses; this plate of air being, by the mere circumstance of thinness or thickness, disposed to reflect or transmit this or that particular colour. From this he concluded, as already observed, that the colours of all natural bodies depended on their density, or the bigness of their component particles. He also constructed a table, wherein the thickness of a plate necessary to reflect any particular colour was expressed in parts of an inch divided into 1,000,000 parts.

Sir Isaac Newton, pursuing his discoveries concerning the colours of thin substances, found that the same were also produced by plates of a considerable thickness. There is no glass or speculum, he observes, how well polished soever, but, besides the light which it refracts or reflects regularly, scatters every way irregularly a faint light; by means of which the polished surface, when illuminated in a dark room by a beam of the sun's light, may easily be seen in all positions of the eye. It was with this scattered light that the colours in the following experiments were produced.

The sun shining into his darkened chamber through a hole in the shutter one inch wide, he let the beam of light fall perpendicularly upon a glass speculum concave on one side and convex on the other, ground to a sphere of five feet eleven inches radius, and quicksilvered over on the convex side. Then, holding a quire of white paper at the centre of the sphere to which the speculums were ground, in such a manner as that the beam of light might pass through a little hole made in the middle of the paper, to the speculum, and thence be reflected back to the same hole, he observed on the paper four or five concentric rings of colours, like rainbows surrounding the hole, very much like those which appeared in the thin plates above mentioned, but larger and fainter. These rings, as they grew larger and larger, became more dilute, so that the fifth was hardly visible; and yet sometimes, when the sun shone very clear, there appeared faint traces of a sixth and seventh.

We have already taken notice, that the thin plates made use of in the former experiments reflected some kinds of rays in particular parts, and transmitted others in the same parts. Hence the coloured rings appeared variously disposed, according as they were viewed by transmitted or reflected light; that is, according as the plates were held up between the light and the eye, or not. For the better understanding of which we subjoin the following table, wherein on one side are mentioned the colours appearing on the plates by reflected light, and on the other those which were opposite to them, and which became visible when the glasses were held up between the eye and the window. We have already observed, that the centre, when the glasses were in full contact, was perfectly transparent. This spot, therefore, when viewed by reflected light, appeared

4

appeared black, because it transmitted all the rays; and for the same reason it appeared white when viewed by transmitted light.

The colours of the rings produced from reflection by the thick plates, followed the order of those produced by transmission through the thin ones; and by the analogy of their phenomena with those produced from the thin plates, Sir Isaac Newton concluded that they were produced in a similar manner. For he found, that if the quicksilver was rubbed off from the back of the speculum, the glass alone would produce the same rings, but much more faint than before; so that the phenomenon did not depend upon the quicksilver, except in as far as, by increasing the reflection at the back of the glass, it increased the light of the coloured rings. He also found that a speculum of metal only, produced none of those rings; which made him conclude, that they did not arise from one surface only, but depended on the two surfaces of the plate of glass of which the speculum was made, and upon the thickness of the glass between them.

From these experiments and observations, it will be easy to understand the Newtonian theory of colours. Every substance in nature seems to be transparent, provided it is made sufficiently thin. Gold, the most dense substance we know, when reduced into thin leaves, transmits a bluish-green light through it. If, therefore, we suppose any body, gold, for instance, to be divided into a vast number of plates, so thin as to be almost perfectly transparent, it is evident that all or greatest part of the rays will pass through the upper plates, and when they lose their force will be reflected from the under ones. They will then have the same number of plates to pass through which they had penetrated before; and thus, according to the number of those plates through which they are obliged to pass, the object appears of this or that colour, just as the rings of colours appeared different in the experiment of the two plates, according to their distance from one another, or the thickness of the plate of air between them.

This theory is adopted by Edward Hufsey Delaval, in his Experimental Inquiry into the cause of the

changes of colours in opaque and coloured bodies. He endeavours to confirm it by a number of experiments on the infusions of flowers of different colours; but his strongest arguments seem to be those derived from the different tinges given to glass by metallic substances. Here he observes, that each metal gives a tinge according to its specific density; the more dense metals producing the less refrangible colours, and the lighter ones those colours which are more easily refrangible. Gold, which is the densest of all metals, imparts a red colour to glass, whenever it can be divided into particles so minute, that it is capable of being mixed with the materials of which glass is made. It seems indifferent by what means it is reduced to this state, nor can it by any means be made to produce another colour. If it is mixed in large masses without being minutely divided, it imparts no colour to the glass, but remains in its metallic form. Lead, the metal whose density is next in order to that of gold, affords a glass of the colour of the hyacinth; a gem whose distinguishing characteristic is, that it is red with an admixture of yellow, the same colour which is usually called *orange*. Glass of lead is mentioned by several authors as a composition proper, without the addition of any other ingredient, for imitating the hyacinth. Silver, next in density to lead, can only be made to communicate a yellow colour to glass. If the metal is calcined with sulphur, it readily communicates this colour. Leaf-silver laid upon red-hot glass likewise tinges it yellow. When we meet with authors who mention a blue or greenish colour communicated by silver, the cause must have been, that the silver used in such processes was mixed with copper. Mr Delaval assures us, from his own experience, that silver purified by the test retains so much copper, that, when melted several times with nitre and borax, it always imparted a green colour at the first and second melting; though afterwards no such colour was obtainable from it. The only colour produced by copper is green. It is indifferent in what manner the copper is prepared in order to tinge the glass, provided it is exposed without any other ingredient to a sufficient degree of heat. If a quantity of salts are added in the preparation, they will, by attenuating the mixture, make the glass incline to blue, the colour next in order; but this happens only when the fire is moderate; for, in a greater degree of heat, the redundant salts, even those of the most fixed nature, are expelled. It is true, that copper is mentioned by some writers as an ingredient in red glass and enamel; but the *red*, which is the colour of the metal not dissolved or mixed with the glass, remains only while the composition is exposed to such a degree of heat as is too small to melt and incorporate it; for, if it be suffered to remain in the furnace a few minutes after the copper is added, the mass will turn out green instead of red. Iron, the metal next in density to copper, is apt to be calcined, or reduced to a ruddy crocus, similar to that rust which it contracts spontaneously in the air. In this state, it requires a considerable degree of heat to dissolve and incorporate it with glass; till that heat is applied, it retains its ruddy colour: by increasing the heat, it passes through the intermediate colours, till it arrives at its permanent one, which is blue; this being effected in the greatest degree of heat

8
Mr Delaval's experiments in confirmation of it.

the glass will bear, without losing all colour whatever. Iron vitrified *per se* is converted into a blue glass. In short, it is indubitable, that iron is the only metal which will, without any addition, impart to the glass a blue colour: for copper will not communicate that colour without the addition of a considerable quantity of salts, or some other matter that attenuates it; and the other metals cannot by any means be made to produce it at all.

9
Sir Isaac's
theory de-
fended by
Dr Priest-
ley.

These are the principal of Mr Delaval's arguments in favour of Sir Isaac Newton's theory of colours being formed by density. Dr Priestley too hath mentioned some which deserve attention. "It was a discovery of Sir Isaac Newton (says he), that the colours of bodies depend upon the thickness of the fine plates which compose their surfaces. He hath shown, that a change of the thickness of these plates occasions a change in the colour of the body; rays of a different colour being thereby disposed to be transmitted through it; and consequently rays of a different colour reflected at the same place, so as to present an image of a different colour to the eye. A variation in the density occasions a variation in the colour; but still a medium of any density will exhibit all the colours, according to the thickness of it. These observations he confirmed by experiments on plates of air, water, and glass. He likewise mentions the colours which arise on polished steel by heating it, as likewise on bell-metal, and some other metalline substances, when melted and poured on the ground, where they may cool in the open air; and he ascribes them to the scoræ or vitrified parts of the metal, which, he says, most metals, when heated or melted, do continually protrude and send out to their surfaces, covering them in the form of a thin glassy skin. This great discovery concerning the colours of bodies depending on the thickness of the fine plates which compose their surfaces, of whatever density these plates may be, I have been so happy as to hit upon a method of illustrating and confirming by means of electrical explosions. A number of these being received on the surface of any piece of metal, change the colour of it to a considerable distance from the spot on which they were discharged; so that the whole circular space is divided into a number of concentric rings, each of which consists of all the prismatic colours, and perhaps as vivid as they can be produced in any method whatever. Upon showing these coloured rings to Mr Canton, I was agreeably surprised to find, that he had likewise produced all the prismatic colours from all the metals, but by a different operation. He extended fine wires of all the different metals along the surfaces of pieces of glass, ivory, wood, &c.; and when the wire was exploded, he always found them tinged with all the colours. They are not disposed in so regular and beautiful a manner as in the rings I produced, but they equally demonstrate that none of the metals thus exploded discovers the least preference to one colour more than to another. In what manner these colours are formed it may not be easy to conjecture. In Mr Canton's method of producing them, the metal, or the calcined and vitrified parts of it, seem to be dispersed in all directions from the plate of explosion, in the form of spheres of a very great variety of sizes, tinged with all the variety of colours,

10
His expe-
riments.

11
Mr Can-
ton's expe-
riments.

and some of them smaller than can be distinctly seen by any magnifier. In my method of making these colours, they seem to be produced in a manner similar to the production of colours on steel and other metals by heat; *i. e.* the surface is affected without the parts of it being removed from their places, certain plates or laminæ being formed of a thickness proper to exhibit the respective colours."

But, however well supported this doctrine of the formation of colours by density may be, we find the same author (Dr Priestley), whom we have just now seen arguing for it in his history of electricity, arguing against it in his history of vision. "There are (says he) no optical experiments with which Sir Isaac Newton seems to have taken more pains than those relating to the rings of colours which appear in thin plates; and in all his observations and investigations concerning them, he discovers the greatest sagacity both as a philosopher and mathematician; and yet in no subject to which he gave his attention, does he seem to have overlooked more important circumstances in the appearances he observed, or to have been more mistaken with regard to their causes. The former will be evident from the observations of those who succeeded him in these enquiries, particularly those of the Abbe Mazeas. This gentleman, endeavouring to give a very high polish to the flat side of an object-glass, happened to be rubbing it against another piece of flat and smooth glass; when he was surprised to find, that after this friction, they adhered very firmly together, till at last he could not move the one upon the other. But he was much more surprised to observe the same colours between these plane glasses that Newton observed between the convex object-glass of a telescope and another that was plane. These colours between the plane glasses, the Abbe observes, were in proportion to their adhesion. The resemblance between them and the colours produced by Newton, induced him to give a very particular attention to them; and his observations and experiments are as follow:

12
Newtonian
theory im-
pugned by
Dr Priest-
ley.

13
Curious ex-
periments
by the Abbe
Mazeas.

"If the surfaces of the pieces of glass are transparent, and well polished, such as are used for mirrors, and the pressure be as equal as possible on every part of the two surfaces, a resistance, he says, will soon be perceived when one of them is made to slide over the other; sometimes towards the middle, and sometimes towards the edges; but wherever the resistance is felt, two or three very fine curve lines will be perceived, some of a pale red, and others of a faint green. Continuing the friction, these red and green lines increase in number at the place of contact, the colours being sometimes mixed without any order, and sometimes disposed in a regular manner. In the last case, the coloured lines are generally concentric circles, or ellipses, or rather ovals, more or less elongated as the surfaces are more or less united. These figures will not fail to appear, if the glasses are well wiped and warmed before the friction.

"When the colours are formed, the glasses adhere with considerable force, and would always continue so without any change in the colours. In the centre of all those ovals, the longer diameter of which generally exceeds ten lines, there appears a small plate of the same figure, exactly like a plate of gold interposed between the glasses; and in the centre of it there is often

often a dark spot, which absorbs all the rays of light except the violet; for this colour appears very vivid through a prism.

" If the glasses are separated suddenly, either by sliding them horizontally over one another, or by the action of fire, as will be explained hereafter, the colours will appear immediately upon their being put together again, without the least friction.

" Beginning by the slightest touch, and increasing the pressure by insensible degrees, there first appears an oval plate of a faint red, and in the midst of it a spot of light green, which enlarges by the pressure, and becomes a green oval, with a red spot in the centre; and this, enlarging in its turn, discovers a green spot in its centre. Thus the red and the green succeed one another in turns, assuming different shades, and having other colours mixed with them, which will be distinguished presently.

" The greatest difference between these colours exhibited between plane surfaces and those formed by curve ones is, that in the former case pressure alone will not produce them, except in the case above mentioned. With whatever force he compressed them, his attempts to produce the colours were in vain without previous friction. But the reason of this plainly was, that without sliding one of the glasses over the other, they could not be brought to approach near enough for the purpose.

" Having made these observations with plates of glass whose sides were nearly parallel, he got two prisms with very small refracting angles; and rubbing them together, when they were so joined as to form a parallelopiped, the colours appeared with a surprising lustre at the places of contact, owing, he did not doubt, to the separation of the rays of light by the prism. In this case, differently coloured ovals appeared, but the plate of gold in them was much whiter, and only appeared yellow about its edges. This plate having a black spot in its centre, was bordered by a deep purple. He could not perceive any violet by his naked eye, but it might be perceived by the help of a lens with a weak light. It appeared in a very small quantity at the confines of the purple and the blue, and seemed to him to be only a mixture of these two colours. It was very visible in each of the coloured rings by inclining the glasses to the light of the moon. Next to the purple and violet appeared blue, orange, red tinged with purple, light green, and faint purple. The other rings appeared to the naked eye to consist of nothing but faint reds and greens; and they were so shaded that it was not easy to mark their terminations. That the order of these may be compared with Newton's, he gives a view of both in the following table:

<i>Order of the Colours in the Plane Glasses.</i>		<i>Order of the Colours in Newt. Object Glasses.</i>

" When these coloured glasses were suspended over the flame of a candle, the colours disappeared suddenly, though the glasses still continued to adhere to one another when they were parallel to the horizon. When they were suffered to cool, the colours returned by degrees to their former places, in the order of the preceding table.

" After this the Abbe took two plates much thicker than the former, in order to observe at his leisure the action of fire upon the matter which he supposed to produce the colours; and observed, that as they grew warm, the colours retired to the edges of the glasses, and there became narrower and narrower till they were reduced to imperceptible lines. Withdrawing the flame, they returned to their place. This experiment he continued till the glasses were bent by the violence of the heat. It was pleasant, he says, to observe these colours glide over the surface of the glass as they were pursued by the flame.

" At the first, our author had no doubt but that these colours were owing to a thin plate of air between the glasses, to which Newton has ascribed them; but the remarkable difference in the circumstances attending those produced by the flat plates, and those produced by the object-glasses of Newton, convinced him that the air was not the cause of this appearance. The colours of the flat plates vanished at the approach of flame, but those of the object-glasses did not. He even heated the latter till that which was next the flame was cracked by the heat, before he could observe the least dilatation of the coloured rings. This difference was not owing to the plane glasses being less compressed than the convex ones; for though the former were compressed ever so much by a pair of forceps, it did not in the least hinder the effect of the flame.

" Afterwards he put both the plane glasses and the convex ones into the receiver of an air-pump, suspending the former by a thread, and keeping the latter compressed by two strings; but he observed no change in the colours of either of them in the most perfect vacuum he could make.

" Notwithstanding these experiments seemed to be conclusive against the hypothesis of these colours being formed by a plate of air, the Abbe frankly acknowledges, that the air may adhere so obstinately to the surface of the glasses as not to be separated from them by the force of the pump; which, indeed, is agreeable to other appearances: but the following experiments of our author make it still more improbable that the air should be the cause of these colours.

" To

"To try the utmost effect of heat upon these coloured plates, after warming them gradually, he laid them upon burning coals; but though they were nearly red, yet when he rubbed them together by means of an iron rod, he observed the same coloured circles and ovals as before. When he ceased to press upon them, the colours seemed to vanish; but when he repeated the friction, they returned, and continued till the pieces of glass began to be red-hot, and their surfaces to be united by fusion.

"When the outward surface of one of his plates of glass was quicksilvered, none of those colours were visible, though the glasses continued to adhere with the same force. This he ascribed to the stronger impression made on the eye by the greater quantity of light reflected from the quicksilver.

"Judging from the resemblance between his experiments and those of Sir Isaac Newton, that the colours were owing to the thickness of some matter, whatever that was, interposed between the glasses, the Abbe, in order to verify his hypothesis, tried the experiment on thicker substances. He put between his glasses a little ball of suet, about a fourth of a line in diameter, and pressed it between the two surfaces, warming them at the same time, in order to disperse the suet; but, though he rubbed them together as before, and used other soft substances besides suet, his endeavours to produce the colours had no effect. But, rubbing them with more violence in a circular manner, he was surprised, on looking at a candle through them, to see it surrounded with two or three concentric rings, very broad, and with very lively delicate colours; namely, a red inclining to a yellow, and a green inclining to that of an emerald. At that time he observed only these two colours; but continuing the friction, the rings assumed the colours of blue, yellow, and violet, especially when he looked through the glasses on bodies directly opposed to the sun. If, after having rubbed the glasses, the thickness was considerably diminished, the colours grew weaker by transmitted light, but they seemed to be much stronger by reflection, and to gain on one side what they lost on the other.

14
Newtonian
hypothesis
opposed.

"Our author was confirmed in his opinion, that there must be some error in Newton's hypothesis, by considering, that, according to his measures, the colours of the plates varied with the difference of a millionth part of an inch; whereas he was satisfied that there must have been much greater differences in the distance between his glasses, when the colours remained unchanged.

"If the colour depended upon the thickness only, he thought that the matter interposed between the glasses ought to have given the same colour when it was reduced to a thin plate by simple fusion as well as by friction, and that, in rubbing two plates together, warming them at different times, and compressing them with a considerable force, other colours would have appeared besides those above mentioned.

"These circumstances made him suspect, that the different thicknesses of the substance interposed between the glasses served only to make them more or less transparent, which was an essential condition in the experiment; and he imagined that the friction diffused over the surface of the thin substance a kind of matter on which the colours are formed by reflec-

ted light: for when he held the plates (which gave the colours when the suet was between them) over the flame of a small candle, the colours fled with great precipitation, and returned to their place without his being able to perceive the least alteration in the suet.

"He was confirmed in his conjectures, by frequently observing, that when the glasses were separated, at the moment the colours disappeared, they were covered with the same greasy matter, and that it seemed to be in the very same state as when they were separated without warming. Besides, having often repeated the same experiment with different kinds of matter, he found that the degree of heat that dispersed the colours was not always sufficient to melt it; which difference was more sensible in proportion as the matter interposed was made thinner.

"Instead of the suet, he sometimes made use of Spanish wax, resin, common wax, and the sediment of urine. He began with Spanish wax, on account of its remarkable transparency in Mr Hanksbee's electrical experiments; but he had much difficulty in making it sufficiently thin by friction, being often obliged to warm his glasses, to seize the moment of fusion, which continued but a short time, and to hazard the burning of his fingers.

"The experiment at length succeeding, the Spanish wax appeared with its opacity and natural colour when it reflected the light, but they both disappeared in the transmitted light. He observed the same rings in it as in the suet; and indeed he could perceive but little difference between the colours of suet, Spanish wax, common wax, or resin; except that this last substance did not make the colours so vivid, on account of the too great transparency of its particles.

"The sediment of urine had something more particular in its appearance, as its colours were more lively. Holding it above the flame, its colours disappeared; and, keeping it in that situation, there were formed, upon its surface, ramifications, like those of the hear-frost, which disappeared as the glasses grew cold. There were the same ramifications both upon the suet and the wax, but they were not so considerable. The glasses which had Spanish wax and resin between them adhered with so much force, that they could not be separated without the help of fire; and when they began to grow warm, they separated with a noise like that of a glass breaking in the fire, though the glasses were not broken, and the matter between them was not melted.

"Separating the glasses which he first used very suddenly, he observed upon their surface very thin vapours, which formed different colours, but presently vanished altogether.

"To try the effect of vapour, he breathed upon one of his plates of glass, and observed that the vapours which adhered to the glasses sometimes formed, before they were entirely dispersed, a surprising variety of colours. This experiment, he observes, does not always succeed at the first trial. The glass must be breathed upon several times, and care must be taken to wipe it every time with one's hand, both to take off the moisture, and also to make upon the glass a kind of furrows, which contribute very much to the variety of colours, by making inequalities in the thicknesses of the vapours. It is necessary, also, that the glasses

glasses on which these experiments are made have no quicksilver upon them.

"When the particles of water which formed this vapour were too thick to exhibit these colours, he struck them several times with his pencil, in order to attenuate them; and then he saw an infinity of small coloured threads which succeeded one another with great rapidity.

"Putting a drop of water between two pieces of common glass, he observed that the compression of them produced no colour; but if, while they were compressed, the water was made to pass from one place to another, it left behind it large spots, red, yellow, green, purple, &c. and the spots assumed different colours with a surprising rapidity, and presented to the eye a most beautiful variety of shades.

"In order to determine with greater certainty whether they were vapours that caused the colours in his first observations, he first breathed upon one of his plates of glass, and then rubbed them against one another, when the colours appeared in the same order as before, but darker, and dispersed in confusion in the places occupied by the vapours; but when he made use of fire to dissipate the watery particles, the colours resumed their lustre.

"Newton, having introduced a drop of water between his two object-glasses, observed, that in proportion as the water insinuated itself between the glasses, the colours grew fainter, and the rings were contracted; and ascribing these colours to the thickness of the plate of water, as he ascribed the former to that of the plate of air, he measured the diameters of the coloured rings made by the plate of water, and concluded that the intervals between the glasses at the similar rings of these two mediums were nearly as three to four; and thence he inferred, that, in all cases, these intervals would be as the sines of the refractions of these mediums.

"The Abbé Mazeas, in order to assure himself whether, agreeable to this rule, the coloured rings of his glasses depended upon the thickness of the water only, dipped one of the edges of his coloured glasses in a vessel of water, having taken care to wipe and warm them well before he produced his colours by friction. The water was a considerable time in rising as high as the glasses; and in proportion as it ascended, he perceived a very thin plate of water, which seemed to pass over the matter which he thought produced the colours, without mixing with it; for beyond this plate of water, he still perceived the colours in the same place and order, but deeper and darker; and holding the glasses above the flame of a candle, he saw the colours go and come several times as he moved them nearer to or farther from the flame. He then moistened both the glasses more than before; and rubbing them as usual, he always saw the same appearance; and seizing the moment when the colours had disappeared to separate the glasses, he always found that they were wet. On this account, he thought that it could not be the water on which the colour depended, but some substance much more sensible to heat. He also thought that these coloured rings could not be owing to the compression of the glasses; or that, if this circumstance did contribute any

thing to them, it served rather to modify than to generate them.

"M. du Tour gave particular attention to the preceding observations of the Abbé Mazeas. He repeated the experiments with some variation of circumstances, particularly comparing them with those of Sir Isaac Newton. He is so far from supposing a plate of air to be necessary to the formation of these coloured rings, that he thinks the reason of their not appearing between the flat plates of glass is the adhering of the air to their surfaces; and that mere pressure is not sufficient to expel it; except, as the Abbé Mazeas observed, the rings had before been made in the same place; in which case, simple apposition without friction is sufficient; the air, probably, not having had time to apply itself so closely to the surface of the glass. The contact of some other substances, M. du Tour observes, is not so prejudicial in this experiment as that of air; for he found, that, if he only gave the plates a slight coating of any kind of grease, the rings would appear without friction. Also dipping them slightly in water, or wiping them with his finger, would answer the same purpose. He verified his conjectures by means of the air-pump: for, dipping two pieces of glass in water, one of which had been wiped, and the other not, the former appeared to have no bubbles adhering to it when the air was exhausted, whereas the other had.

"When one of the glasses is convex, our author observes, that the particles of air may more easily make their escape by pressure only; whereas their retreat is in a manner cut off when they are compressed between two flat surfaces. The air-pump, he found, was not able to detach these particles of air from the surfaces to which they adhere; leaving these flat plates for a considerable time in an exhausted receiver, was not sufficient to prepare them so well for the experiment, as wiping them.

"Besides the observations on the colours of thin plates, it has been seen that Sir Isaac Newton imagined he could account for the colours exhibited by thick ones in some cases in a similar manner; particularly in those curious experiments in which he admitted a beam of light through a hole in a piece of pasteboard, and observed the rings of colours reflected back upon it by a concave glass mirror of equal thickness in all places. These experiments were resumed, and happily pursued, by the Duke de Chaulnes, who ascribed these colours to the inflection of light*. Chance led the duke to observe, that when the nearer surface of the glass mirror was clouded by breathing upon it, so as lightly to tarnish it, a white diffused and vivid light was seen upon the pasteboard, and all the colours of the rings became much stronger, and more distinct. This appearance he made constant by moistening the surface of the mirror with a little milk and water, and suffering it to dry upon it.

"In all his experiments upon this subject, he found, that when the rays fell converging on the surface of the mirror, the rings were hardly visible; when they fell parallel upon it, as they must have done in all the experiments of Newton, they appeared sufficiently distinct; but when, by means of a convex lens placed in the hole of the window, they were made to diverge from

ments on
colours by
reflection.

* See Op-
tics.

from the centre of the sphere to which the mirror was ground, so that they fell perpendicularly on the surface of the mirror, the colours were as vivid as he could make them. In this case he could remove the reflected image to a great distance from the hole, without making the rings disappear; and he could plainly perceive them to arise from their central spots, which changed their colours several times.

"The effect of tarnishing the mirror convinced him, that these coloured rings depended on the first surface of the mirror; and that the second surface, or that which reflected them after they had passed the first, only served to collect them and throw them upon the pasteboard in a quantity sufficient to make them visible, and he was confirmed in his supposition by the following experiments.

"He took a plano-convex object-glass, of six feet focus, and placed it six feet from the pasteboard with its convex side towards it. By this means the rays which fell upon that surface, after being refracted there, were transmitted through the thickness of the glass, parallel to one another, and fell perpendicularly on the plane surface that reflected them, and, in their return, would be collected upon the pasteboard. In these circumstances the rings appeared very distinct after he had tarnished the convex surface, which in this position was next to the light.

"Turning the same glass the contrary way, so that the plane surface was towards the pasteboard, he could perceive none of the rings at the distance of six feet; but they were visible at the distance of three feet: because at that distance the second surface reflected the rays by its concavity directly towards the pasteboard.

"These two experiments demonstrate the use of the second surface of the mirror, and show the manner of placing it to most advantage. Those that follow show the use of the first surface with respect to these rings; and he was led to make them by the casual observation above mentioned.

"Newton, he observes, had remarked, that when he made use of a mirror of the same focus with the first he had used, but of twice the thickness, he found the diameter of the rings much smaller than before. This observation the duke thought favourable to his own conclusions; for if these rings depend upon the first surface, the nearer it is to the second, which only reflects the ray transmitted from it, the larger they ought to appear upon the pasteboard.

"To ascertain this fact, he thought of making use of two moveable surfaces; and to make use of a micrometer to measure the distance between them with exactness. For this purpose he took a metallic mirror belonging to a reflecting telescope, being part of a sphere of ten feet radius; and he fixed it firm upon a foot in which was a groove that carried a light frame, to which was fastened a thin piece of talc tarnished with milk and water. The frame that supported the piece of talc could either be brought into contact with the mirror, or be removed to the distance of eight or nine inches from it, and the micrometer showed to the utmost exactness the least motion of the frame.

"Having placed this mirror ten feet from the pasteboard, that is, at the distance of the radius of its own sphere, he observed the rings to appear very distinct;

N^o 79.

the form of his mirror being very true: but the diameter of the rings upon the pasteboard varied with the distance of the talc from the mirror; so that they were very large when the talc was near the mirror, and very small when it was placed at the distance of seven or eight inches.

"These experiments proved, that the rings were formed by the first surface, and reflected by the second; but it still remained to be determined in what manner they were formed. He imagined, that the small pencils of rays that were transmitted through the pores of the glass, or any other transparent substance, might suffer a kind of inflection, which might change the cylinder which they formed into a truncated cone, either by means of their different degrees of inflexibility, or by the different distances at which they pass by the edges of the small hole through which they are transmitted. Pursuing this idea, he thought of making use of some body, the pores of which were of a known and determined shape. Instead, therefore, of the piece of talc, he placed a piece of fine linen in the above mentioned frame, stretching it as even as possible, to make the pores formed by the threads more exact and more permeable by the light; and he soon found, with great pleasure, that his conjecture was verified: for, instead of the circular rings which he had before, they were now manifestly square, though their angles were a little rounded; and they were coloured as the others, though the light was not very vivid, on account of the quantity that was stopped by the muslin.

"When, instead of the muslin, he stretched across his frame fine silver wires exactly parallel, at the distance of about three quarters of a line, or a whole line from one another, without any other wires across them; instead of the rings which he had seen before, there was nothing upon the pasteboard but a gleam of white light divided by many small streaks, coloured in a very vivid manner, and in the same manner as the rings."

Thus we have another hypothesis of the formation of colours, namely, by the inflection of light in its passage out from between the solid and impenetrable particles of which bodies are composed. It is, however, very difficult, upon the hypothesis either of Sir Isaac Newton, or that of the Duke de Chaulnes, to give a reason why bodies that are not entirely white, should not appear variously coloured. For, it appears from Sir Isaac Newton's experiments, that plates of different density are capable of exhibiting the same colours; and that where a plate is continually varying in density, it will produce all the colours. Now it is evident, that the plates of which we suppose all natural bodies to be composed, must be similar to one that is perpetually varying in its thickness; for supposing the plates of which any substance is composed to be of any determinate thickness, 9 millionth parts of an inch for instance; such of the rays as are reflected from this plate will be red. But if any of them penetrate to the depth of $11\frac{1}{2}$ of these parts, they will be reflected of a violet colour, &c. and thus must alloy and obscure the red; and so of others. If we suppose the colours to be produced by inflection, it will be equally difficult to account for some particular rays being inflected and others not; seeing we observe

17
Another theory of colours.

serve that all of them are capable of being inflected by every substance whatever, when they pass very near it. In some cases too, colours are produced when the light is neither refracted nor inflected, as far as we can judge; and this seems to obscure the theory of chromatics more than any thing we have yet mentioned.

As the experiments we are now about to mention are of the greatest importance, and in direct terms contradict one of Sir Isaac Newton's, we shall give a full account of them, from Priestley's history of Vision, &c. with his remarks thereon.

18
One of Sir Isaac Newton's experiments found to be erroneous.

The experiment in question is the eighth of Newton's second book of Optics: "He (Sir Isaac Newton) found, he says, that when light goes out of air through several contiguous refracting mediums, as through water and glass, and thence goes out again into air, whether the refracting surfaces be parallel or inclined to one another, that light, as often as, by contrary refractions, it is so corrected, that it emerges in lines parallel to those in which it was incident, continues ever after to be white: but if the emergent rays be inclined to the incident, the whiteness of the emerging light will, by degrees, in passing on from the place of emergence, become tinged at its edges with colours. This he tried by refracting light with prisms of glass, placed within a prismatic vessel of water.

"By theorems deduced from this experiment, he infers, that the refraction of the rays of every sort, made out of any medium into air, are known by having the refraction of the rays of any one sort; and also, that the refraction out of one medium into another is found as often as we have the refractions out of them both into any third medium.

* *Swed. Abhand.*
vol. 16.
p. 300.

"On the contrary, a Swedish philosopher (M. Klingenskierna) observes*, that, in this experiment, the rays of light, after passing through the water and the glass, though they come out parallel to the incident rays, will be coloured; but that the smaller the glass prism is, the nearer will the result of it approach to Newton's description.

"This paper of M. Klingenskierna, being communicated to Mr Dollond by M. Mallet, made him entertain doubts concerning Newton's report of the result of his experiment; and determined him to have recourse to experiments of his own.

"He therefore cemented together two plates of parallel glass, at their edges, so as to form a prismatic vessel when stopped at the ends or bases; and the edge being turned downwards, he placed in it a glass prism with one of its edges upwards, and filled up the vacancy with clear water; so that the refraction of the prism was contrived to be contrary to that of the water, in order that a ray of light, transmitted through both these refracting mediums, might be affected by the difference only between the two refractions. As he found the water to refract more or less than the glass prism, he diminished or increased the angle between the glass plates, till he found the two contrary refractions to be equal, which he discovered by viewing an object through this double prism. For when it appeared neither raised nor depressed, he was satisfied that the refractions were equal, and that the emergent rays were parallel to the incident.

VOL. IV. Part II.

"Now, according to the prevailing opinion, he observes, that the object should have appeared through this double prism in its natural colour; for if the difference of refrangibility had been in all respects equal, in the two equal refractions, they would have rectified each other. But this experiment fully proved the fallacy of the received opinion, by showing the divergency of the light by the glass prism to be almost double of that by the water; for the image of the object, though not at all refracted, was yet as much inflected with prismatic colours, as though it had been seen through a glass wedge only whose angle was near 30 degrees.

19
Colours produced without refraction or reflection.

"This experiment is the very same with that of Sir Isaac Newton above mentioned, notwithstanding the result was so remarkably different: but Mr Dollond assures us, that he used all possible precaution and care in his process; and he kept his apparatus by him, that he might evince the truth of what he wrote, whenever he should be properly required to do it.

"He plainly saw, however, that if the refracting angle of the water-vessel could have admitted of a sufficient increase, the divergency of the coloured rays would have been greatly diminished, or entirely rectified; and that there would have been a very great refraction without colour, as he had already produced a great discolouring without refraction: but the inconveniency of so large an angle as that of the prismatic vessel must have been, to bring the light to an equal divergency with that of the glass prism, whose angle was about 60°, made it necessary to try some experiments of the same kind with smaller angles.

"Accordingly he got a wedge of plate-glass, the angle of which was only nine degrees; and, using it in the same circumstances, he increased the angle of the water-wedge, in which it was placed, till the divergency of the light by the water was equal to that by the glass; that is, till the image of the object, though considerably refracted by the excess of the refraction of the water, appeared nevertheless quite free from any colours proceeding from the different refrangibility of the light.

"Notwithstanding it evidently appeared, I may say to almost all philosophers, that Mr Dollond had made a real discovery of something not comprehended in the optical principles of Sir Isaac Newton, it did not appear to so sensible a man, and so good a mathematician, as Mr Murdoch is universally acknowledged to be. Upon this occasion he interposed in the defence, as he imagined, of Sir Isaac Newton; maintaining, that Mr Dollond's positions, which he says, he knows not by what mishap have been deemed paradoxes in Sir Isaac's theory of light, are really the necessary consequences of it. He also endeavours to show, that Sir Isaac might not be mistaken in his account of the experiment above mentioned. But admitting all that he advances in this part of his defence, Newton must have made use of a prism with a much smaller refracting angle than, from his own account of his experiments, we have any reason to believe he ever did make use of.

20
Defences of Sir Isaac.

"The fact probably was, that Sir Isaac deceived himself in this case, by attending to what he imagined to be the clear consequences of his other experiments; and though the light he saw was certainly tinged with colours,

colours, and he must have seen it to be so, yet he might imagine that this circumstance arose from some imperfection in his prisms, or in the disposition of them, which he did not think it worth his while to examine. It is also observable, that Sir Isaac is not so particular in his description of his prisms, and other parts of his apparatus, in his account of this experiment, as he generally is in other cases, and therefore probably wrote his account of it from his memory only.

P. 804. "Much has been said on this experiment; and it is thought very extraordinary that a man of Sir Isaac's accurate attention should overlook a circumstance, the effect of which now appears to be so considerable. But it has happily occurred to Mr Michell, that, as Sir Isaac Newton observes he used to put saccharum saturni into his water to increase its refractive power, the lead, even in this form, might increase the dissipative refraction, as it does in the composition of glass; and if so, that this would account for Newton's not finding the dissipative power of water less than that of his glass prisms, which he otherwise ought to have done, if he had tried the experiment as he said he did.

"Accordingly he included a prism of glass in water, as highly impregnated with saccharum saturni as it would bear, the proportion of saccharum to water being about as 5 to 11. When the image, seen through the water (so impregnated) and a glass prism, was in its natural place, it still was coloured, though very little: he thought not more than a fourth part as much as when seen through plain water, and the prism in its natural place; so that he had no doubt, but that, if his prism had had a little less of the dispersing power, its errors would have been perfectly corrected."

21
Mr Delaval's experiments on the colours of opaque bodies.

Besides the experiments of Mr Delaval above related, and which were made on the colours of transparent bodies, he has lately published an account of some made upon the permanent colours of opaque substances; the discovery of which must be of the utmost consequence in the arts of colour-making and dyeing. These arts, he observes, were in very remote ages carried to the utmost height of perfection in the countries of Phœnicia, Egypt, Palestine, India, &c. and that the inhabitants of these countries also excelled in the art of imitating gems, and tinging glass and enamel of various colours. The colours used in very ancient paintings were as various as those now in use, and greatly superior both in beauty and durability. The paints used by Apelles were so bright, that he was obliged to glaze his pictures with a dark-coloured varnish, lest the eye should be offended by their excessive brightness; and even these were inferior to what had been used among the ancient Egyptians. Pliny complains that the art of painting was greatly decayed in his time; and the moderns were not furnished with any means of retrieving the art until they began to avail themselves of experimental observations.

The changes of colour in permanently coloured bodies, our author observes, are produced by the same laws which take place in transparent colourless substances; and the experiments by which they can be investigated consist chiefly of various methods of uniting the colouring particles into larger, or dividing them into smaller masses. Sir Isaac Newton made his experiments chiefly on transparent substances; and in the few places where he treats of others, acknowledges his deficiency of experiments. He makes the following remark, however, on those bodies which reflect one kind of light and transmit another, viz. that "if these glasses or liquors were so thick and massy that no light could get through them, he questioned whether they would not, like other opaque bodies, appear of one and the same colour in all positions of the eye; though he could not yet affirm it from experience." It was the opinion of this great philosopher, that all coloured matter reflects the rays of light, some reflecting the more refrangible and others the less refrangible rays more copiously; and that this is not only a true reason of these colours, but likewise the only reason. He was likewise of opinion that opaque bodies reflect the light from their anterior surface by some power of the body evenly diffused over and external to it. With regard to transparent coloured liquors, he expresses himself in the following manner: "A transparent body which looks of any colour by transmitted light, may also look of the same colour by reflected light; the light of that colour being reflected by the farther surface of that body, or by the air beyond it: and then the reflected colour will be diminished, and perhaps cease, by making the body very thick, and pitching it on the back-side to diminish the reflection of its farther surface, so that the light reflected from the tinging particles may predominate. In such cases the colour of the reflected light will be apt to vary from that of the light transmitted."

To investigate the truth of these opinions Mr Delaval entered upon a course of experiments with transparent coloured liquors and glasses, as well as with opaque and semitransparent bodies. From these he discovered several remarkable properties of the colouring matter; particularly, that in transparent coloured substances it does not reflect any light; and when, by intercepting the light which was transmitted, it is hindered from passing through such substances, they do not vary from their former colour to any other, but become entirely black (A).

This incapacity of the colouring particles of transparent bodies to reflect light, being deduced from very numerous experiments, may therefore be held as a general law. It will appear the more extensive, if we consider that, for the most part, the tinging particles of liquors or other transparent substances are extracted from opaque bodies; that the opaque bodies owe their colours to those particles, in like manner as the transparent substances do; and that by the loss of them they are deprived of their colours.

For making his experiments, Mr Delaval used small
vials

(A) Here our author observes, that he makes use of the word *colour* only to express those called *primary*; such a mixture of them as does not compose whiteness, or any of the gradations between white and black, such as are called by Sir Isaac Newton, grey, dun, or russet brown.

22
These colours depend chiefly on the division of the colouring particles.

23
No light reflected by the colouring particles.

24 Apparatus for making these experiments.

vials of flint glass, whose form was a parallelopiped, and their height, exclusive of the neck, about two inches, the base about an inch square, and the neck two inches in length. The bottom and three sides of each of these vials was covered with a black varnish; the cylindrical neck, and the anterior side, except at its edges, being left uncovered. He was careful to avoid any crevices in the varnish, that no light might be admitted except through the neck or anterior side of the vials.

In these experiments it is of importance to have the vials perfectly clean; and as many of the liquors are apt to deposit a sediment, they ought to be put into the vials only at the time the experiments are to be made. The uncovered side of the vials should not be placed opposite to the window through which the light is admitted; because in that situation the light would be reflected from the farther side of the vial; and our author observes that smooth black substances reflect light very powerfully. But as it is a principal object in the experiment that no light be transmitted through the liquor, this is best accomplished by placing the uncovered side of the vial in such a situation that it may form a right angle with the window.

25 The colouring matter only shows itself by transmitted light.

With these precautions our author viewed a great number of solutions, both of coloured metallic salts and of the tinging matter of vegetables; universally observing, that the colour by reflection was black, whatever it might be when viewed by transmitted light. If these liquors, however, are spread thin upon any white ground, they appear of the same colour as when viewed by transmitted light; but on a black ground they afford no colour, unless the black body be polished; in which case the reflection of the light through it produces the same effect as transmission.

The experiments with tinged glasses were in many respects analogous to those with transparent coloured liquors. For these he made several parcels of colourless glass, principally using one composed of equal parts of borax and white sand. The glass was reduced to powder, and afterwards ground, together with the ingredients by which the colours were imparted. "This method (says he) of incorporating the tinging particles is greatly preferable to mixing them with the raw materials; and the glasses thus composed excel most others in hardness, being scarcely inferior in lustre to real gems."

The result of all the experiments made in this manner was, that when matter is of such thinness, and the tinge so dilute, that light can be transmitted through it, the glasses then appear vividly coloured; but when they are in larger masses, and the tinging matter is more densely diffused through them, they appear black; for these, as well as the transparent coloured liquors, show their colour only by transmission. The following experiments were made with a view to determine the proportion of tinging matter which produces colour or blackness.

26 Experiments to determine the proportion of tinging matter.

1. Glass was tinged green by adding to it $\frac{1}{80}$ th of its weight of copper; and that whether the latter was used in its metallic or calcined state.

2. A blue glass was made by the addition of zaffre, a purple one by manganese, a red glass by gold, and yellow glasses by silver and calcined iron. A yellow glass resembling a topaz was likewise made by the ad-

dition of a small quantity of charcoal in powder. The same colour was likewise procured by the addition of wheat-flour, rosin, and several other inflammable matters. Small pieces of each of these glasses being ground by a lapidary, resembled gems of their different colours.

3. Having formed pieces of such glasses about two inches thick, he inclosed them in black cloth on all sides except their farther and anterior surfaces. In this situation each of them showed a vivid colour when light was transmitted through them; but when the posterior surface was likewise covered with the cloth to prevent this transmission, no other colour than black was exhibited by any of them.

4. When plates of transparent coloured glass, somewhat thicker than common window-glass, were made use of, they always exhibited their colours by transmitted light.

5. On intercepting the light transmitted through these coloured plates, they as constantly appeared black when placed in such a direction as to form a right angle with the window.

From these phenomena Mr Delaval deduced the following observations: 1. That the colouring particles do not reflect any light. 2. That a medium, such as Sir Isaac Newton has described, is diffused over both the anterior and farther surfaces of the plates, whereby objects are equally and regularly reflected as by a mirror. Hence, when it is said that light is reflected by the surface of any substance, it should be understood from this expression, that the reflection is effected by the medium diffused over its surface.

6. When a lighted candle is placed near one of those coloured plates, the flame is reflected by the medium which is diffused over the anterior surface. The image thus reflected entirely resembles the flame in size and colour; being scarcely diminished, and not in the least tinged by the coloured glass. 27 On the reflection of the light of a candle by coloured glasses.

7. If the plate be not so intensely coloured, or so massy, as to hinder the transmission of the light of the candle, there appears a secondary image of the flame, which is reflected by the medium contiguous to the farther surface of the glass; and as the light thus reflected passes through the coloured glass, it is tinged very vividly.

8. When the glass used in this experiment is of a green colour, the image of the flame is always of a bright green; and when glasses of other colours are used, that of the secondary flame is always the same with that of the glass.

9. The secondary image is less than that reflected from the anterior surface. This diminution is occasioned by the loss of that part of the light which is absorbed in passing through the coloured glass. For whenever any medium transmits one sort of rays more copiously than the rest, it stops a great part of the differently coloured rays. Much more light also is lost in passing through coloured than transparent substances. In making these observations, it is proper to choose coloured plates of glass which are not in every part of an equal thickness, that the secondary image may not coincide with that reflected from the anterior surface, and be intercepted by it.

10. When the plates are so thick, and so copiously coloured, that the light cannot penetrate to their farther

ther surface, they appear intensely black in whatever direction they are viewed, and afford no secondary image, but only reflect, from their anterior surface, the flame, or any other objects that are opposed to them. These objects are represented in their own proper colours, and are as free from tinge as those reflected from quicksilvered glass, or specula made of white metals.

Hence again it is manifest, that the colouring particles do not possess any share of reflective power; for if they had any share in this reflection, they would certainly impart some share of colour to the light they reflected. Hence also it appears, that transparent coloured bodies, in a solid state, possess no more reflective power than those in a fluid state.

Experiments on
the pure
colouring
particles.

Our author next considers the colouring particles themselves, pure, and unmixed with other media. In order to procure masses made up of such particles, several transparent coloured liquors were reduced to a solid consistence by evaporation. By employing a gentle heat, the colouring matter may thus remain unimpaired; and is capable of having its particles again separated by water or other liquids, and tinging them as before.

In this state the colouring particles reflect no light, and therefore appear uniformly black, whatever substance they have been extracted from. In the course of his experiments, Mr Delaval made use of the infusions of brazil wood, logwood, fustic, turmeric, red saunders, alkanet, sap-green, kermes, and all the other transparent coloured liquors he had tried before, among which were infusions of red and yellow flowers, without observing the least variation in the result.

Some liquors are apt to become totally opaque by evaporation; the reason of which may be the crystallization of saline matters, or the coalescence of the particles into masses, differing considerably in density from the menstrua in which they were dissolved. When this opacity takes place, our author has constantly observed, that they become incapable of entering the pores of wool, silk, or other matters of that kind, or of adhering to their surface; and consequently unfit for the purposes of dyeing. This he supposes to arise from their increased bulk; for the attractive force by which the particles cohere together is weakened in proportion as their bulk increases; so that the degree of magnitude of the colouring particles, which is essential to the opacity of liquors, is inconsistent with the minuteness requisite for dyeing. An instance of this is given in an infusion of fustic. Having infused some of this wood in such a quantity of water, that the latter was saturated with the colouring particles, he evaporated the liquor to a solid consistence with an uninterrupted, but very gentle heat. During every part of the process the liquor continued transparent, and the solid extract yielded by it transmitted a yellow colour when spread thin, but appeared black when thicker masses were viewed. Having prepared another pint of this liquor, he evaporated half the water, and allowed the remainder to become cold. In this state it became turbid and opaque; on filtering, a transparent tincture passed through, an opaque fecula remaining on the paper. This fecula did not adhere to the paper,

but was easily separable from it: on being dried, it appeared white with a slight tinge of yellow; but was nevertheless soluble in water, and by solution gave a liquid in all respects similar to the original infusion. "From these circumstances (says he) it appears that a given proportion of water, or a sufficient degree of heat, is requisite to the solution of the colouring particles of fustic. And experience evinces, that those particles which are too gross to pass through filtering paper, are incapable of entering the pores or firmly cohering to the surface of bodies. Many ingredients, such as the colouring particles of logwood, kermes, and various other matters, are soluble in water in every proportion; and therefore their infusions are not subject to become opaque or turbid during their evaporation. The solid extracts obtained by evaporation reflect no colour, but are black.

Our author also formed solid masses by mixing a small quantity of drying oil with pigments which consist chiefly of colouring matter; as Prussian blue, indigo, and sap-green. These paints likewise exhibit their respective colours only by transmitted light; appearing entirely black when viewed by reflection. Instances of blackness arising from this density of the colouring matter may be observed in several kinds of fruits, as black currants, cherries, &c. for the juices of these appear red when spread thin on a white ground, or otherwise viewed by transmitted light.

Mr Delaval's next attempt was to consider the action and properties of the colouring particles of opaque bodies themselves, and the means by which these colours are produced. Here our author endeavours to prove, that these colours of opaque bodies appear on the same principles as those already mentioned, which seem black when very dense, but show their proper tinge when spread thin upon a white ground. On this subject the following experiments were made.

1. Grass, and other green leaves of plants, were digested in rectified spirit of wine; by which means a transparent green tincture was obtained. One of the vials formerly mentioned being filled with this liquid, it was observed to transmit a vivid green colour; but the other part of the tincture, which was contiguous to the uncovered side of the vial, reflected no light, and therefore appeared black.

2. Having poured some of the tincture into a China cup, the bottom was thereby made to look green, exactly resembling the colour which had been extracted from the leaves.

3. After the colour had been totally abstracted by the vinous spirit, the leaves remained apparently unaltered, either as to figure or texture; but were entirely white, or had their whiteness slightly tinged with brown.

4. Red, purple, and blue flowers, were also digested in spirit of wine; all of which yielded their colouring matter to the spirit, and became white by being deprived of it. From most of these flowers, however, the spirit acquired either no tinge at all, or only a very faint one; but when acidulated, it became red, and by the addition of an alkali appeared blue, purple, or green, according to the quantity of alkali and the nature of the infusion. In these states, all of them, when viewed.

viewed by transmitted light, or poured upon a white ground, showed their colours, but universally appeared black by reflection.

5. Red, purple, and blue flowers, were digested in water slightly acidulated with nitrous acid. Thus, red infusions were obtained, which, by saturation with sea-salt, might be preserved for many years.

6. The same liquors were changed green, blue, or purple, by the addition of an alkali: but here the case was the same as before; all of them yielding vivid colours by transmission, but none by reflection. In making this experiment, care must be taken to add the alkali very gradually; for if too much is put in at once to the red liquor, the intermediate colours between the red and the green will be wanting. To half an ounce of the red infusion it is proper to add, at once, only the smallest quantity that can be taken up on the point of a pen; repeating this addition slowly, until each of the colours be produced.

7. The flowers, after having been repeatedly macerated in acidulated water, lost their colouring matter, and became white.

8. Yellow flowers also communicated their colours to water and to spirit of wine. The infusions and tinctures of these flowers were subjected to the same experiments as had been employed in the examination of the liquors already mentioned; and appeared yellow by transmitted light, but did not reflect any colour.

9. White paper, linen, &c. may be tinged of any of these colours, by dipping them in the infusions; and the consideration of the manner in which the colours are imparted to the linen, affords much insight into the manner in which natural colours are produced. It has already been observed, that, when the colouring matter of plants is extracted from them, the solid fibrous parts, thus divested of their covering, display their natural whiteness. White linen, paper, &c. are formed of such fibrous vegetable matter; which is bleached by dissolving and detaching the heterogeneous colouring particles. When these are dyed or painted with vegetable colours, it is evident that they do not differ in their manner of acting on the rays of light from natural vegetable bodies; both yielding their colours by transmitting, through the transparent coloured matter, the light which is reflected from the white ground. This white matter frequently exists, without any considerable mixture, in plants, while they are in a state of vegetation; as cotton, white flowers, the pith, wood, seeds, roots, and other parts of several kinds of vegetables. When decayed trees, &c. have been long exposed to the atmosphere, their coloured juices are sometimes so perfectly extracted, that the fibres appear white. This white matter is not distinct from the vegetable earth to which plants are reduced by burning†. Mr Deleval has rendered ashes intensely white, by carefully calcining them, and afterwards grinding with a small proportion of nitre, and exposing them to such a degree of heat as would cause the nitre to deflagrate with the remaining quantity of phlogiston. Lastly, the ashes were digested with marine acid, in order to dissolve the ferruginous matter diffused through them, and repeatedly washing the remainder in water. Mixing ashes thus purified with borax, and applying a vitrifying

heat, an opaque enamel is obtained, remarkable for its whiteness.

Hence it appears, that the earth which forms the substance of plants is white, and separable from that substance which gives to each its peculiar colour; that whenever it is pure and unmixed, or diffused through colourless media, it shows its native whiteness; and is the only vegetable matter endowed with a reflective power. It may be discovered, however, by other means than that of burning: thus, roses may be whitened by exposing them to the vapour of burning sulphur; an effect which cannot be attributed to the vitriolic acid, but to the phlogiston contained in that vapour. This was proved to be the case, by exposing several kinds of red and purple flowers to the phlogistic vapour issuing from *hepar sulphuris*; and by this every one of them was whitened; their colour being afterwards restored by the addition of an acid either mineral or vegetable.

“Thus (says Mr Delaval) it appears, that the colouring matter of the flowers is not discharged or removed, but only dissolved by the phlogiston; and thereby divided into particles too minute to exhibit any colour. In this state, together with the vegetable juice in which they are diffused, they form a colourless transparent covering, through which the white matter of the flowers is seen untinged. The colouring particles of plants consist principally of inflammable matter; and their solubility in phlogiston, and union with it, are analogous to the action of other inflammable bodies upon each other. Thus, ether dissolves all essential and expressed oils, animal empyreumatic oils, and resins. Sulphur, camphor, and almost all substances abounding in phlogiston, are soluble in oils, ardent spirits, or other inflammable menstrua. The manner in which the red colour of vegetable flowers is restored, appears to be explicable from known chemical laws. When acids are applied to the whitened flowers, they unite with the phlogiston which the sulphur had communicated, and disengage it from the colouring particles; which, being thus extricated, resume their original magnitude and hue. A change of the same kind is also produced by fixed alkali, which, like the acids, has a strong attraction for phlogiston, always changes the whitened flowers to a blue, purple, or green colour.

“In like manner, the action of the rays of light operates upon coloured bodies. Thus, dyed silk, or other substances of that kind, when exposed to the sun's light, are deprived of their colour in every part on which the rays are allowed to act; whilst those preserve their colour which are defended from the light by the folds of the cloth, or intervention of any opaque body. The colours, thus impaired, may be restored if acids are applied while the injury is recent; but they are afterwards apt to fly off, on account of that volatility which is constantly imparted by inflammable matter to any other with which it is united.”

Our author now proceeds, at considerable length, to prove the identity of the solar light and phlogiston; but as recent experiments have shown that these two are essentially distinct, we omit his argumentation upon this head. The error of his theory in this respect, however, does not in the least affect the doctrine concerning colours above laid down: on the contrary, the latest

Colours destroyed by the light of the sun.

latest experiments have determined, that phlogiston, in its grossest form, *viz.* that of common charcoal, manifests a surprising power of whitening various substances; which, according to Mr Delaval's theory, proceeds from the power it has of dissolving the colouring matter with which they are impregnated. This solvent power, according to our author, is manifest in many other instances besides those already mentioned. Silk is whitened by the phlogistic vapours of sulphur: and this operation does not appear to differ from the change effected on flowers by the same vapour. The light of the sun is found to be a necessary and essential agent in bleaching linen, wax, and various other substances; some part of the colouring matter which impairs the whiteness of these bodies not yielding to any other solvent. Red flowers are whitened by the electric spark, of whose inflammable nature we cannot entertain the least doubt; for the spark itself is a bright flame, and yields the same smell which all other phlogistic matters impart. The electric spark, in like manner, changes the blue infusion of turnsole to red (B). The effects which it produces on the turnsole, and on red flowers, do not differ from each other, except in degree only. For when vegetable matter is dissolved, it is changed from blue to red; and, when farther dissolved, it is divided into particles too minute to exhibit any colour.

³³
How to distinguish the solutions made by phlogiston from those made by acids.

Solutions effected by means of phlogiston frequently are wrongly attributed to the operation of supposed acid menstrua, as several kinds of substances are capable of being dissolved indiscriminately both by acids and phlogiston. For the purpose of distinguishing, therefore, in any case between the action of the acid solvents and that of the inflammable menstrua, it is proper to examine the nature of the matter by which either of these principles are furnished. It appears from various chemical processes, that alkalies are rendered mild, and capable of crystallization, in proportion as they are united to phlogiston. The phlogisticated alkaline lixivium, when saturated, is perfectly mild; and by a slight evaporation is reduced to a concrete crystalline mass, which does not deliquesce or imbibe the least moisture from the air, and no longer retains any alkaline property. M. Beaumé, by an elegant and ingenious experiment, has proved the presence of phlogiston in mild alkalies, and has shown that their power of crystallizing depends upon their union with that principle. He heated in a silver vessel a lixivium of mild alkali, which imparted to the silver a covering or coating of inflammable matter, by which its surface was tarnished and became black. The lixivium was several times poured out of the silver vessel; and after the surface of the metal had been freed from the tarnish, the lixivium was replaced in it, and again heated, by which the tarnish was renewed; and this was repeated till the lixivium no longer communicated any stain to the silver. The causticity of the lixivium was increased in proportion as it imparted its phlogiston to the silver; and at the end of the process the alkali became perfectly caustic, and incapable of crystallizing.

Our author now goes on to prove, that fixed air is

not an acid, nor a compound of air and phlogiston, as is now generally believed, but rather entirely of a phlogistic nature. For an account of his arguments in favour of this opinion, see the article FIXED AIR: here we shall only consider his farther experiments on colours.

"From the preceding experiments (says he) it appears, that the colouring particles of flowers and leaves are soluble in acid, alkaline, and phlogistic menstrua. The other parts of vegetables consist of materials similar to those which are contained in their flowers and leaves, and undergo the same changes from the same causes. Having extracted from logwood its colouring particles by repeatedly boiling it in water, the wood was thus deprived of its yellow colour, and assumed a brown hue similar to that of oak-wood. Some pieces of it thus deprived of its colour were then macerated in aquafortis; and after they had undergone the action of that acid, they were washed in a sufficient quantity of water. The wood was thus reduced to whiteness."

Here our author observes, that though most authors who treat of colouring substances describe logwood as of a red colour, he was never able to procure any other colour from it but yellow. It imparts yellow and orange colours to distilled water. Other waters extract a red tinge from it by means of the alkali which they contain. These observations are also applicable to the other dyeing woods, kermes, and various other articles of the materia tinctoria. By a similar treatment, fustic wood also lost its colouring matter, and became white.

The results of all the experiments above related are, that the colouring matter of plants does not exhibit any colour by reflection, but by transmission only; that their solid earthy substance is a white matter; and that it is the only part of vegetables which is endowed with a reflective power; that the colours of vegetables are produced by the light reflected from this white matter, and transmitted from thence through the coloured coat or covering which is formed on its surface by the colouring particles; that whenever the colouring matter is either discharged or divided by solution into particles too minute to exhibit any colour, the solid earthy substance is exposed to view, and displays that whiteness which is its distinguishing characteristic.

Mr Delaval next proceeds to examine the coloured parts of animal substances, and finds them exactly similar, with regard to the manner in which the colour is produced, to the vegetable bodies already treated of. The tinctures and infusions of cochineal and of kermes yield their colours when light is transmitted through them, but show none by reflection. On diluting fresh ox-gall with water, and examining it in the phials already mentioned, that part of it which was in the neck of the phial, and viewed by transmitted light, was yellow; but the anterior surface was black, and reflected no colour. Flesh derives its colour entirely from the blood, and when deprived of it the fibres and vessels are perfectly white; as are likewise the membranes

³⁴
Logwood affords only a yellow tincture with water.

³⁴
Colouring matter of animal substances.

(B) This effect of the electric spark is now known to be produced, not by its phlogistic nature, but by the generation of an acid.

branes, sinews, and bones, when freed from their aqueous and volatile parts; in which case they are a mere earth, unalterable by fire, and capable of imparting an opaque whiteness to glass.

³⁵
Of the colour of blood.

On examining blood diluted with water in one of the phials formerly described, it transmitted a red colour, and the anterior surface was almost, but not entirely, black; for it received a slight hue of brown from some coagulated particles that were suspended in the liquor. In order to procure blood sufficiently diluted, and at the same time equably and perfectly dissolved, he mixed as much cruor with spirit of sal ammoniac as imparted a bright colour to it. The liquor being then viewed in the phial, that part which was contained in the neck, and transmitted the light, appeared of a fine red; but the anterior part reflecting no light, was intensely black. Hence it appears, that the florid red colour of the flesh arises from the light which is reflected from the white fibrous substance, and transmitted back through the red transparent covering which the blood forms on every part of it.

Blood, when recently drawn, does not assume the appearance common to transparent coloured liquors; for these, when too massy to transmit light from their farther surfaces, always appear black; but blood, when recently drawn, always shows a fine red colour, in whatever way it be viewed. This is occasioned by a white matter diffused through the blood; and which is easily separated from the cruor, by dividing it after coagulation into a number of thin pieces, and washing in a sufficient quantity of pure water. Thus the water acquires a red colour, and ought to be changed daily. In a few days it will acquire no more tinge; and the remaining masses of the cruor are no longer red, but white.

³⁶
Of the shells of lobsters.

In like manner, the red colour of the shells of lobsters, after boiling, is no more than a mere superficial covering spread over the white calcareous earth of which the shells are composed, and may be easily removed from the surface by scraping or filing. Before the application of heat, this superficial covering is much denser; inasmuch that, in some parts of the shell, it appears quite black, being too thick to admit the passage of the light to the shell and back again; but where this transparent blue colour of the unboiled lobster is thinner, it constantly appears like a blue film. In like manner, the colours of the eggs of certain birds are entirely superficial, and may be scraped off, leaving the white calcareous earth exposed to view.

³⁷
Of feathers.

The case is the same with feathers, which owe their colours entirely to a very thin layer of some transparent matter upon a white ground. Our author ascertained this by scraping off the superficial colours from certain feathers which were strong enough to bear the operation; and thus separated the coloured layers from the white ground on which they had been naturally spread. The lateral fibres of the feathers cannot indeed have their surfaces separated in this manner; but their texture, when viewed by a microscope, seems to indicate, that the colours are produced on them by no other means than those already related. In the examination of some animal subjects where the colouring matter could not be separated by chemical means, our author had recourse to mechanical division; but this can only be employed when the principal part of the

white substance is unmixed with the coloured coat or covering which is spread upon its surface. All of them, however, by whatever means their colours could be separated, showed that they were produced in the same manner, namely, by the transmission of light from a white ground through a transparent coloured medium.

The coloured substances of the mineral kingdom are ³⁸ Of the colours of mineral substances. very numerous, and belong principally to two classes, viz. earths and metals. The former, when pure, are all perfectly white, and their colours arise from phlogistic or metallic mixtures. Calcareous earths, when indurated, constitute marble, and may be tinged with various colours by means of metallic solutions; all which are similar in their nature to the dyes put upon silk, cotton, or linen, and invariably proceed from the same cause, viz. the transmission of light through a very thin and transparent coloured medium. Flints are formed from siliceous earths, and owe their colour to phlogiston. When sufficiently heated, they are rendered white by the loss of the inflammable matter which produced their colour. When impregnated with metals, they form agates, cornelians, jasper, and coloured crystals. The coloured gems also receive their different hues from metals; and all of them may be imitated by glasses tinged with such phlogistic or metallic matters as enter into the composition of the original substances.

Thus our author concludes, that the coloured earths, ³⁹ Of metals. gems, &c. exhibit their various tints in the same manner with other substances; viz. by the transmission of light reflected from a white ground. Our author, however, proceeds farther; and asserts, that even the colours of metals themselves are produced in the same manner.

"Gold (says he) exhibits a white light, which is tinged with yellow. I have used this expression, because it appears from experiment that gold reflects a white light, and that its yellow colour is a tinge superadded to its whiteness. The experiment is thus set forth by Sir Isaac Newton. Gold in this light (that is, a beam of white light) appears of the same yellow colour as in day light; but by intercepting at the lens a due quantity of the yellow-making rays, it will appear white like silver, as I have tried; which shows, that its yellowness arises from the excess of the intercepted rays, tinging that whiteness with their colour when they are let pass.

"I have already shown, by numerous experiments, in what manner coloured tinges are produced; and it uniformly appears, from all these experiments, that colours do not arise from reflection, but from transmission only. A solution of silver is pellucid and colourless. A solution of gold transmits yellow, but reflects no colour. This metal also, when united with glass, yields no colour by reflection, but by transmission only. All these circumstances seem to indicate, that the yellow colour of gold arises from a yellow transparent matter, which is a constituent part of that metal; that it is equally mixed with the white particles of the gold, and transmits the light which is reflected by them, in like manner as when silver is gilt, or foils are made by covering white metals with transparent colours. But these factitious coverings are only superficial; whereas the yellow matter of gold is diffused throughout the whole substance of the metal, and

and appears to envelope and cover each of the white particles. In whatsoever manner the yellow matter of gold is united to its white substance, it exists in a rare state; for it bears only the same proportion to the white particles of the gold as that of the yellow-making rays which were intercepted bears to all the other rays comprised in the white light of the sun.

"Sir Isaac Newton has shown, that when spaces or interstices of bodies are replenished with media of different densities, the bodies are opaque; that those superficies of transparent bodies reflect the greatest quantity of light which intercede media that differ most in their refractive densities; and that the reflections of very thin transparent substances are considerably stronger than those made by the same substances of a greater thickness. Hence the minute portions of air, or of the rarer medium, which occupies spaces void of other matter, reflect a vivid white light whenever their surfaces are contiguous to media whose densities differ considerably from their own; so that every small mass of air, or of the rarer medium, which fills the pores or interstices of dense bodies, is a minute white substance. This is manifest in the whiteness of froth, and of all pellucid colourless bodies; such as glass, crystal, or salts, reduced to powder, or otherwise flawed: for in all these instances a white light is reflected from the air or rarer medium which intercede the particles of the denser substances whose interstices they occupy."

From these principles our author takes occasion to explain the reason why the particles of metals which yield no colour by incident light when suspended in their solvents, are disposed to exhibit colours when separated from them. Hence also we see why opaque white substances are rendered pellucid by being reduced to uniform masses whose component parts are every where nearly of the same density; for as all pellucid substances are rendered opaque and white by the admixture of pellucid colourless media of considerably different densities, they are again deprived of their opacity by extricating these media which kept their particles at a distance from each other: thus froth or snow, when resolved into water, lose their whiteness, and assume their former pellucid appearance. In like manner, by proper fluxes, the opaque white earths are reduced to pellucid colourless glasses; because all reflections are made at the surfaces of bodies differing in density from the ambient medium, and in the confines of equally dense media there is no reflection.

As the calces of metals are enabled to reflect their colours by the intervention of the particles of air; so, when mixed with oil in the making of paints, they always assume a darker colour, because the excess of the density of oil over that of air forms a sensible difference when comparatively considered with respect to the specific gravity of the rarer metals. From this cause perceptibly less light is reflected from the molecularæ of oil than from those of air, and consequently the mass appears darker. The case, however, is different with such paints as are formed of the denser metals; as vermilion, minium, &c.: for though oil differs very considerably from air in its specific density, yet it also differs very much in this respect from the denser metallic powders; and the molecularæ of oil which divide their particles act upon the light so strongly, that the reflection occasioned by them cannot be distinguished

from those which are caused by rarer media. Hence, though we mix vermilion or minium with oil, the colour is not sensibly altered.

This part of our author's theory, however, seems liable to objection: for though it be true that the calces of some metals are denser than others, yet that is, comparatively speaking, but in a very small proportion; nor is even the difference of density between oil and the calces of the heavier metals at all comparable to that between the density of air and oil. Thus, tho' the calx of iron may be 10 or 11 times more dense than oil; yet, as the latter is between 500 and 600 times denser than air, the small difference between the oil and metallic calx ought to be imperceptible. In this respect, indeed, there are considerable differences with regard to the oils employed, which cannot be supposed to arise from the mere circumstance of density. Thus the colour of vermilion, when mixed with turpentine-varnish, is much brighter than with linseed-oil; and yet the difference between the densities of linseed-oil and turpentine-varnish is very trifling. The mere action of heat likewise has a surprising effect in this case. Thus the red calx of iron, called *scarlet oker*, by being only heated a certain degree, appears of a very dark purple, resuming its red colour when cold; and this variation may be induced as often as we please by only heating it over the fire in a shovel. In like manner, by gradually heating red lead, it may be made to assume a most beautiful crimson colour; which growing gradually darker, becomes at last almost quite black. On cooling, if the heat has not been raised too high, it gradually returns through the same shades of colour, until at last it fixes in its original hue. These immense differences in colour cannot by any means be attributed either to the expulsion of air or to an alteration in density. The fire indeed does certainly expand these calces as well as other bodies; but as the medium interspersed between their particles is thus also expanded, the colour ought at least to remain the same, if not to become lighter, on account of the superior expansion of air to that of metal by the same degree of heat. It would seem, therefore, that the action of the element of fire itself has a considerable share in the production of colours; and indeed its share in the operations of nature is so great, that we might well think it strange if it should be entirely excluded from this.

With regard to semipellucid substances, which appear of one colour by incident and another by transmitted light, our author likewise endeavours to show, that no reflection is made by the coloured matter, but only by the white or colourless particles. They consist of pellucid media, throughout which white or colourless opaque particles are dispersed. The latter are disposed at such distances from each other, that some of the incident rays of light are capable of passing through the intervals which intercede them, and thus are transmitted through the semipellucid mass. Some sorts of rays penetrate through such masses, while others which differ from them in their refrangibility are reflected by the white or colourless particles; and from thence are transmitted through the pellucid part of the medium which intervenes between the reflecting particles and the anterior surface of the mass. On the same principle our author explains the blue colour of the

substances.

42
How colours are shown by transmitted light.

the sky, the green colour of the sea, and other natural phenomena; and from his numerous experiments on this subject at last concludes, "that the power by which the several rays of light are transmitted through different media is inherent in the particles themselves, and therefore is not confined to the surfaces of such media. For if the transmissive force was exerted at the surface only, the thinner plates of coloured substances would act upon the rays as powerfully as thicker masses. But it appears from experiment, that in proportion as the rays pass through different thicknesses of coloured media, they exhibit colours differing not only in degree, but frequently in species also.

"The sun's light, by which bodies are illuminated, consists of all the rays by which a white light is compounded. These rays, in their entire and undivided state, are incident upon the opaque particles of semipellucid substances, and upon the colouring particles of transparent-coloured substances, whenever these media are exposed to the light. When the rays accede to the opaque particles of semipellucid substances, some sorts of them are reflected back from the anterior surface of those particles: the other sorts of rays, which are not reflected back, are diverted from the direction which is opposite to the anterior surface of the opaque particles, and passing through the intervals between the particles, are transmitted through the mass.

"When the rays are incident upon the particles of transparent-coloured bodies, none of them are reflected back; because the colouring particles are not endowed with any reflective power: but some of the rays are either stopped at the anterior surface of the particles, or are diverted into such directions as render them incapable of passing towards the farther side of the mass; and consequently such rays cannot be transmitted. The rays which are not thus intercepted or dispersed, are transmitted in the same manner as those which pass through semipellucid media. Thus it is evident, that the coloured rays which are transmitted through semipellucid substances are *inflected* by the opaque particles; and those which are transmitted through transparent-coloured substances are *inflected* by the colouring particles. From the preceding observations likewise it appears, that the particles of coloured media inflect the several sorts of rays according to the several sizes and densities of the particles; also in proportion to the inflammability of the media which owe their colour to them; and it is manifest that the transmission of coloured rays depends upon their inflection. All these observations are conformable to Sir Isaac Newton's doctrine, that the rays of light are reflected, refracted, and inflected, by one and the same principle acting variously in various circumstances."

43
Of the manner in which light is reflected from white bodies.

The most remarkable part of Mr Delaval's doctrine is that concerning the metals; for the better understanding of which we shall premise a short abstract of his general doctrine concerning white bodies, and the manner in which light is reflected by them. "All the earths (he observes), which in their natural state are of a pure white, constitute transparent colourless media when vitrified with proper fluxes, or when dissolved in colourless menstrua; and the saline masses obtainable from their solutions are transparent and colourless while they retain the water which is essential to their

crystallization, and are not flawed or reduced to powder; but after their pores and interstices are opened in such a manner as to admit the air, they become then white and opaque by the entrance of that rare medium. The earthy particles which form the solid parts of bodies generally exceed the others in density; consequently these particles, when contiguous to the rare media already mentioned, must reflect the rays of light with a force proportionate to their density. The reflective power of bodies does not depend merely upon their excess of density, but upon their difference of density with respect to the surrounding media. Transparent colourless particles, whose density is greatly inferior to that of the media they come between, also powerfully reflect all sorts of rays, and thereby become white. Of this kind are the air or other rare fluids which occupy the interstices of liquors; and in general of all denser media into whose interstices such rare particles are admitted.

"Hence we may conclude, that white opaque bodies are constituted by the union or contiguity of two or more transparent colourless media differing considerably from each other in their reflective powers. Of these substances we have examples in froth, emulsions, or other imperfect combinations of pellucid liquors, milk, snow, calcined or pulverized salts, glass or crystal reduced to powder, white earths, paper, linen, and even those metals which are called white by mineralogists and chemists: for the metals just mentioned do not appear white unless their surfaces be rough; as in that case only there are interstices on their surface sufficient to admit the air, and thus make a reflection of a white and vivid light.

"But the polished surfaces of metallic mirrors reflect the incident rays equably and regularly, according to their several angles of incidence; so that the reflected rays do not interfere with each other, but remain separate and unmixed, and therefore distinctly exhibit their several colours. Hence it is evident, that white surfaces cannot act upon the light as mirrors; because all the rays which are reflected from them are blended in a promiscuous and disorderly manner.

"The above-mentioned phenomena give much insight into the nature and cause of opacity; as they clearly show, that even the rarest transparent colourless substances, when their surfaces are adjacent to media differing greatly from them in refractive power, may thereby acquire a perfect opacity, and may assume a resplendency and hue so similar to that of white metals, that the rarer pellucid substances cannot by the sight be distinguished from the dense opaque metals. And this similarity to the surfaces of metals occurs in the rare pellucid substances, not only when, from the roughness of their surfaces, they resemble unpolished metals in whiteness, but also when, from their smoothness, they resemble the polished surfaces of metals.

"Metals seem to consist entirely of transparent matter, and to derive their apparent opacity and lustre solely from the copious reflection of light from their surfaces. The analogy between the metals and transparent media, as far as respects their optical properties, will appear from the following considerations.

"1. All metals dissolved in their proper menstrua are

transparent. 2. By the union of two or more transparent media, substances are constituted which are similar to metals in their opacity and lustre, as plumbago and marcasites. 3. The transparent substances of metals, as well as those of minerals, by their union with phlogiston, acquire their strong reflective powers from which their lustre and opacity arise. 4. The surfaces of pellucid media, such as glass or water, assume a metallic appearance, when by their smoothness, difference of density with respect to the contiguous media, or any other cause, they are disposed copiously to reflect the light.

"From all these considerations it is evident, that opaque substances are constituted by the union or contiguity of transparent colourless media, differing from one another in their reflective powers; and that, when the common surface, which comes between such media, is plane, equal, and smooth, it reflects the incident rays equally and regularly as a mirror; but when the surface is rough and unequal, or divided into minute particles, it reflects the incident rays irregularly and promiscuously in different directions, and consequently appears white."

45
Theory of
colours still
uncertain.

From all these experiments we can only conclude, that the theory of colours seems not yet to be determined with certainty; and very formidable, perhaps unanswerable, objections, might be brought against every hypothesis on this subject that hath been invented. The discoveries of Sir Isaac Newton, however, are sufficient to justify the following

A P H O R I S M S.

1. All the colours in nature proceed from the rays of light.
2. There are seven primary colours; which are red, orange, yellow, green, blue, indigo, and violet.
3. Every ray of light may be separated into the seven primary colours.
4. The rays of light in passing through the same medium have different degrees of refrangibility.
5. The difference in the colours of light arises from its different refrangibility: that which is the least refrangible producing red; and that which is the most refrangible violet.
6. By compounding any two of the primary colours, as red and yellow, or yellow and blue, the intermediate colour, as orange or green, may be produced.
7. The colours of bodies arise from their dispositions to reflect one sort of rays, and to absorb the other: those that reflect the least refrangible rays appearing red; and those that reflect the most refrangible, violet.
8. Such bodies as reflect two or more sorts of rays appear of various colours.
9. The whiteness of bodies arises from their disposition to reflect all the rays of light promiscuously.
10. The blackness of bodies proceeds from their incapacity to reflect any of the rays of light (c).

Entertaining EXPERIMENTS, founded on the preceding Principles.

- I. Out of a single colourless ray of light to produce seven other rays, which shall paint, on a white body, the seven primary colours of nature.

PROCURE of an optician a large glass prism DEF, ^{Plate} well polished, two of whose sides must contain an angle ^{CXXXV.} of about sixty-four degrees. Make a room quite dark, ^{fig. 1.} and in the window shutter AB, cut a round hole, about one-third of an inch in diameter, at C, through which a ray of light LI passing, falls on the prism DEF: by that it is refracted out of the direction IT, in which it would have proceeded into another GH; and, falling on the paper MNSX, will there form an oblong spectrum PQ, whose ends will be semicircular, and its sides straight; and if the distance of the prism from the paper be about eighteen feet, it will be ten inches long, and two inches wide. This spectrum will exhibit all the primary colours: the rays between P and V, which are the most refracted, will paint a deep violet; those between V and I, indigo; those between I and B, blue; those between B and G, green; those between G and Y, yellow; those between Y and O, orange; and those between O and R, being the least refracted, an intense red. The colours between these spaces will not be every where equally intense, but will incline to the neighbouring colour: thus the part of the orange next to R, will incline to a red; that next to Y, to a yellow: and so of the rest.

- II. From two or more of the primary colours, to compose others that shall, in appearance, resemble those of the former.

By mixing the two homogeneous colours red and yellow, an orange will be produced, similar in appearance to that in the series of primary colours; but the light of the one being homogeneous, and that of the other heterogeneous, if the former be viewed through a prism it will remain unaltered, but the other will be resolved into its component colours red and yellow. In like manner other contiguous homogeneous colours may compound new colours; as by mixing yellow and green, a colour between them is formed; and if blue be added, there will appear a green that is the middle colour of those three. For the yellow and blue, if they are equal in quantity, will draw the intermediate green equally toward them, and keep it, as it were, in equilibrio, that it verge not more to the one than to the other. To this compound green there may be added some red and violet; and yet the green will not immediately cease, but grow less vivid; till by adding more red and violet it will become more diluted; and at last, by the prevalence of the added colours, it will be overcome, and turned into some anomalous colour.

If the sun's white, composed of all kinds of rays, be added

(c) From hence it arises, that black bodies, when exposed to the sun, become sooner heated than all others.

added to any homogeneous colour, that colour will not vanish, nor change its species, but be diluted; and by adding more white, it will become continually more diluted. Lastly, if red and violet be mixed, there will be generated, according to their various proportions, various purples, such as are not like, in appearance, to the colour of any homogeneous light; and of these purples, mixed with blue and yellow, other new colours may be composed.

III. *Out of three of the primary colours, red, yellow, and blue, to produce all the other prismatic colours, and all that are intermediate to them.*

will be all the intermediate colours, as the marygold, aurora, &c.

IV. *By means of the three primary colours, red, yellow, and blue, together with light and shade, to produce all the gradations of the prismatic colours.*

On seven square panes of glass, paste papers that are painted with the seven prismatic colours, in the same manner as in the last experiment. The colours for the orange, green, indigo, and violet, may be made by mixing the other three. Then with bistre (F), well diluted, shade a sheet of very thin paper, by laying it light on both its sides. With pieces of this paper cover four-fifths of a glass, of the same size with the others, by laying one piece on the four lowest divisions, another on the three lowest, a third on the two lowest, and the fourth on the lowest division only, and leaving the top division quite uncovered. When one of the coloured glasses is placed in the box, together with the glass of shades, so that the side AB of the one be applied to the side BC of the other, as in fig. 3. the several gradations of colours will appear shaded in the same manner as a drapery judiciously painted with that colour.

It is on this principle that certain French artists have proceeded in their endeavours to imitate, by designs printed in colours, paintings in oil: which they do by four plates of the same size, on each of which is engraved the same design. One of these contains all the shades that are to be represented, and which are painted either black, or with a dark grey. One of the three other plates is coloured with blue, another with red, and the third with yellow; each of them being engraved in those parts only which are to represent that colour (G); and the engraving is either stronger or weaker, in proportion to the tone of colour that is to be represented (H).

These four plates are then passed alternately under the press, and the mixture of their colours produces a print that bears no small resemblance to a painting. It must be confessed, however, that what has been hitherto done of this kind falls far short of that degree of perfection of which this art appears susceptible. If they who engrave the best in the manner of the crayon were to apply themselves to this art, there is reason to

5 A 2

expect

Fig. 2. PROVIDE three panes of glass of about five inches square; and divide each of them, by parallel lines, into five equal parts. Take three sheets of very thin paper; which you must paint, lightly, one blue, another yellow, and the third red (D). Then paste on one of the glasses five pieces of the red paper; one of which must cover the whole glass, the second only the four lower divisions, the third the three lower, the fourth the two lowest, and the fifth the last division only. On the other two glasses five pieces of the blue and yellow papers must be pasted in like manner. You must also have a box of about six inches long, and the same depth and width as the glasses; it must be black on the inside: let one end be quite open, and in the opposite end there must be a hole large enough to see the glasses completely. It must also open at the top, that the glasses may be placed in it conveniently.

When you have put any one of these glasses in the box, and the open end is turned toward the sun, you will see five distinct shades of the colour it contains. If you place the blue and yellow glasses together, in a similar direction, you will see five shades of green distinctly formed. When the blue and red glasses are placed, a bright violet will be produced; and by the red and yellow, the several shades of orange.

Fig. 3. If, instead of placing these glasses in a similar position, you place the side AB of the yellow glass against the side BD of the blue, you will see all the various greens that are produced by nature (E); if the blue and red glasses be placed in that manner, you will have all the possible varieties of purples, violets, &c.; and, lastly, if the red and orange glasses be so placed, there

(D) Water-colours must be used for this purpose: the blue may be that of Prussia, and very bright; the red, carmine; and the yellow, gamboge, mixed with a little saffron. These colours must be laid very light and even, on both sides of the paper.

(E) In the first position of the glasses, the quantity of blue and yellow being equal, the same sort of green was constantly visible: but by thus inverting the glasses, the quantity of the colours being constantly unequal, a very pleasing variety of tints is produced.

(F) The bistre here used must be made of foot, not that in stone.

(G) When a red drapery is required, it is engraved on the plate assigned to that colour; and so of yellow and blue: but if one of the other colours be wanting, suppose violet, it must be engraved on those that print the red and blue: and so of the rest. The plates of this kind have been hitherto engraved in the manner of mezzotinto; but these, unless they are skilfully managed, soon become smutty. Engravings in the manner of the crayon will perhaps answer better.

(H) The principal difficulty in this sort of engraving arises from a want of a skilful management, in giving each plate that precise degree of engraving which will produce the tone of colour required. If a bright green is to be represented, there should be an equal quantity of graving on the red and yellow plates: but if an olive green, the yellow plate should be engraved much deeper than the red.

expect they would produce far more finished pieces than we have hitherto seen.

V. *To make figures appear of different colours successively.*

Fig. 4. MAKE a hole in the window-shutter of a dark room, through which a broad beam of light may pass, that is to be refracted by the large glass prism ABC, which may be made of pieces of mirrors cemented together, and filled with water. Provide another prism DEF, made of three pieces of wood; through the middle of this there must pass an axis on which it is to revolve. This prism must be covered with white paper; and each of its sides cut through in several places, so as to represent different figures, and those of each side should likewise be different. The inside of this prism is to be hollow, and made quite black, that it may not reflect any of the light that passes through the sides into it. When this prism is placed near to that of glass, as in the figure, with one of its sides EF perpendicular to the ray of light, the figures on that side will appear perfectly white: but when it comes into the position *gb*, the figures will appear yellow and red; and when it is in the position *kl*, they will appear blue and violet. As the prism is turned round its axis, the other sides will have a similar appearance. If instead of a prism a four or five sided figure be here used, the appearances will be still further diversified.

This phenomenon arises from the different refrangibility of the rays of light. For when the side EF is in the position *gb*, it is more strongly illuminated by the least refrangible rays; and wherever they are predominant, the object will appear red or yellow. But when it is on the position *kl*, the more refrangible rays being then predominant, it will appear tinged with blue and violet.

VI. *The solar magic lantern.*

PROCURE a box, of about a foot high, and eighteen inches wide, or such other similar dimensions as you shall think fit; and about three inches deep. Two of the opposite sides of this box must be quite open; and in each of the other sides let there be a groove, wide enough to pass a stiff paper or pasteboard. This box must be fastened against a window on which the sun's rays fall direct. The rest of the window should be closed up, that no light may enter. Provide several sheets of stiff paper, which must be blacked on one side. On these papers cut out such figures as you shall think proper: and placing them alternately in the grooves of the box, with their blacked sides towards you, look at them through a large and clear glass prism; and if the light be strong, they will appear to be painted with the most lively colours in nature. If you cut on one of these papers the form of the rainbow, about three quarters of an inch wide, you will have a lively representation of that in the atmosphere.

This experiment may be further diversified, by pasting very thin papers, lightly painted with different colours, over some of the parts that are cut out: which will appear to change their colours when viewed through the prism, and to stand out from the paper, at different distances, according to the different degrees of refrangibility of the colours with which

they are painted. For greater convenience, the prism may be placed in a stand on a table, at the height of your eye, and made to turn round on an axis, that when you have got an agreeable prospect, you may fix it in that position.

VII. *The prismatic camera obscura.*

Fig. 5. MAKE two holes F, *f*, in the shutter of a dark chamber, near to each other; and against each hole place a prism ABC, and *abc*, in a perpendicular direction, that their spectrums NM may be cast on the paper in a horizontal line, and coincide with each other; the red and violet of the one being in the same part with those of the other. The paper should be placed at such a distance from the prisms that the spectrum may be sufficiently dilated. Provide several papers nearly of the same dimensions with the spectrum, cross these papers, and draw lines parallel to the divisions of the colours. In these divisions cut out such figures as you shall find will have an agreeable effect, as flowers, trees, animals, &c. When you have placed one of these papers in its proper position, hang a black cloth or paper behind it, that none of the rays that pass through may be reflected and confuse the phenomenon. The figures cut on the paper will then appear strongly illuminated with all the original colours of nature. If while one of the prisms remains at rest, the other be revolved on its axis, the continual alteration of the colours will afford a pleasing variety; which may be further increased by turning the prism round in different directions.

When the prisms are so placed that the two spectrums become coincident in an inverted order of their colours, the red end of one falling on the violet end of the other; if they be then viewed through a third prism DH, held parallel to their length, they will no longer appear coincident, but in the form of two distinct spectrums, *pt* and *nm* (fig. 6.), crossing one another in the middle, like the letter X: the red of one spectrum and the violet of the other, which were coincident at NM, being parted from each other by a greater refraction of the violet to *p* and *m*, than that of the red to *n* and *t*.

This experiment may be further diversified by adding two other prisms, that shall form a spectrum in the same line, and contiguous to the other; by which not only the variety of figures, but the vicissitude of colours, will be considerably augmented.

VIII. *The diatonic scale of colours.*

THE illustrious Newton, in the course of his investigations of the properties of light, discovered that the length of the spaces which the seven primary colours possess in the spectrum, exactly corresponds to those of chords that found the seven notes in the diatonic scale of music. As is evident by the following experiment.

Fig. 7. On a paper in a dark chamber, let a ray of light be largely refracted into the spectrum AFIMGP, and mark the precise boundaries of the several colours, as *a*, *b*, *c*, &c. Draw lines from those points perpendicular to the opposite side, and you will find that the spaces *MrfF*, by which the red is bounded; *rgcf*, by which the orange is bounded; *qp ed*, by which the yellow is bounded, &c. will be in exact proportion

Improved,
CIRCUMFERENTOR.

A. Belli Prin. Wal. sculptor fecit.

to the divisions of a musical chord for the notes of an octave; that is, as the intervals of these numbers 1, $\frac{8}{9}$, $\frac{5}{6}$, $\frac{1}{4}$, $\frac{2}{3}$, $\frac{1}{5}$, $\frac{9}{6}$, $\frac{1}{2}$.

IX. *Colorific music.*

FATHER CASTEL, a Frenchman, in a curious book he has published on chromatics, supposes the note *ut* to answer to blue in the prismatic colours; the note *re* to yellow, and *mi* to red. The other tones he refers to the intermediate colours; from whence he constructs the following gamut of colorific music:

Ut	Blue
Ut sharp	Sea-green
Re	Bright green
Re sharp	Olive green
Mi	Yellow
Fa	Aurora
Fa sharp	Orange
Sol	Red
Sol sharp	Crimson
La	Violet
La sharp	Blue Violet
Si	Sky blue
Ut	Blue

This gamut, according to his plan, is to be continued in the same manner for the following octave; except that the colours are to be more vivid.

He supposes that these colours, by striking the eye in the same succession as the sounds (to which he makes them analogous) do the ear, and in the same order of time, they will produce a correspondent sensation of pleasure in the mind. It is on these general principles, which F. Castel has elucidated in his treatise, that he has endeavoured, though with little success, to establish his ocular harpsichord.

The construction of this instrument, as here explained, will show that the effects produced by colours by no means answer those of sounds, and that the principal relation there is between them consists in the duration of the time that they respectively affect the senses.

Fig. 8. Between two circles of pasteboard, of ten inches diameter, AB and CD, inclose a hollow pasteboard cylinder E, 18 inches long. Divide this cylinder into spaces half an inch wide, by a spiral line that runs round it from top to bottom, and divide its surface into six equal parts by parallel lines drawn between its two extremities; as is expressed in the figure.

Let the circle AB, at top, be open; and let that at bottom, CD, be closed, and supported by an axis or

screw, of half an inch diameter, which must turn freely in a nut placed at the bottom of a box we shall presently describe. To the axis just mentioned adjust a wooden wheel G, of two inches and a half in diameter, and that has 12 or 15 teeth, which take the endless screw H. Let this cylinder be inclosed in a box ILMN (fig. 9.) whose base is square, and at whose bottom there is a nut in which the axis F turns. Observe that the endless screw H should come out of the box, that it may receive the handle O, by which the cylinder is to be turned.

This box being closed all round, place over it a tin covering A, which must be perforated in different parts; from this cover there must hang three or four lights, so placed that they may strongly illumine the inside of the cylinder. In one side of this box (which should be covered with pasteboard) cut eight apertures, *a, b, c, d, e, f, g, h*, of half an inch wide, and $\frac{1}{3}$ of an inch high; they must be directly over each other, and the distance between them must be exactly two inches. It is by these openings, which here correspond to the musical notes, that the various colours analogous to them are to appear; and which being placed on the pasteboard cylinder, as we have shown, are reflected by means of the lights placed within it.

Fig. 9.

It is easy to conceive, that when the handle O is turned, the cylinder in consequence rising half an inch, if it be turned five times round, it will successively show, at the openings made in the side of the box, all those that are in the cylinder itself, and which are ranged according to the direction of the inclined lines drawn on it. It is therefore according to the duration of the notes which are to be expressed, that the apertures on the cylinder are to be cut. Observe, that the space between two of the parallel lines drawn vertically on the cylinder, is equal to one measure of time; therefore, for every turn of the cylinder, there are six measures, and thirty measures for the air that is to be played by this instrument.

The several apertures being made in the side of the cylinder, in conformity to the notes of the tune that is to be expressed, they are to be covered with double pieces of very thin paper, painted on both sides with the colours that are to represent the musical notes.

This experiment might be executed in a different manner, and with a much greater extent; but as the entertainment would not equal the trouble and expence, we have thought it sufficient to give the above piece, by which the reader will be enabled to judge how far the analogy supposed by F. Castel really exists.

Chronic,
Chronicle.

CHRONIC, or CHRONICAL, among physicians, an appellation given to diseases that continue a long time; in contradistinction to those that soon terminate and are called *acute*.

CHRONICLE, in matters of literature, a species or kind of history disposed according to the order of time, and agreeing in most respects with annals. See ANNALS.

Parian CHRONICLE. See ARUNDELIAN Marbles. Since that article was printed, in which an abstract was given

of Mr Robertson's doubts and observations respecting the authenticity of the Parian Chronicle, one or two publications have since appeared in answer, but none of them calculated to remove the objections or materially to affect the arguments that had been stated with so much learning and ingenuity against it. The following strictures, however, with which the Monthly Reviewers have concluded their critique of Mr Robertson's performance, seem to merit consideration.

Chronicle.

Chronicle.

Monthly
Review,
Jan. 1789.

On Objection I. *That the characters have no certain or unequivocal marks of antiquity*, the Reviewers remark, that this seems rather to be an answer to a defender of the inscription, than an objection. If a zealous partizan of the marble should appeal to its characters and orthography, as decisive proofs of its being genuine, it would be proper enough to answer, that these circumstances afford no certain criterion of authenticity. But in this word *certain* sculks an unlucky ambiguity. If it means demonstrative, it must be allowed that no inscription can be proved to be certainly genuine from these appearances; but if it means no more than highly probable, many inscriptions possess sufficient internal evidence to give their claims this degree of certainty. The true question is, Has not the Parian Chronicle every mark of antiquity that can be expected in a monument claiming the age of 2000 years? The letters Π and Ξ are, by Mr R.'s own confession, such as occur in genuine inscriptions; and to say in answer, that an impostor might copy the forms of these letters from other inscriptions, is already to suppose the inscription forged, before it is rendered probable by argument. The learned author of the Dissertation seems to betray some doubt of his own conclusion; for he adds, p. 56. "that the antiquity of an inscription can never be proved by the mere form of the letters, because the most ancient characters are as easily counterfeited as the modern." But this objection is equally applicable to all other ancient inscriptions; and is not to the purpose, if the present inscription has any peculiar marks of imposture in its characters and orthography. "The characters do not resemble the Sigeian, the Nemean, or the Delian inscriptions." Mr R. answers this objection himself, by adding, "which are supposed to be of a more ancient date." The opposite reason to this will be a sufficient answer to the other objection, "that they do not resemble the Farnesian pillars or the Alexandrian MS." If "they differ in many respects from the Marmor Sandvicense," they may be presumed to agree in many. "They seem to resemble, more than any other, the alphabet taken by Montfaucon from the Marmor Cyzicenum." Thus it appears that the Parian Chronicle most nearly resembles the two inscriptions, to whose age it most nearly approaches.

When Mr R. adds, that the letters "are such as an ordinary stone-cutter would probably make, if he were employed to engrave a Greek inscription, according to the alphabet now in use," he must be understood *cum grano salis*. The engraver of a fac simile generally omits some nice and minute touches in taking his copy; but, even with this abatement, we dare appeal to any adept in Greek calligraphy, whether the specimen facing p. 56, will justify our author's observation? "The small letters (ο, ο, ω) intermixed among the larger, have an air of affectation and artifice." Then has the greater part of ancient inscriptions an air of affectation and artifice. For the ο is perpetually engraved in this diminutive size; and ω being of a kindred sound, and ο of a kindred shape, how can we wonder that all three should be represented of the same magnitude? In the inscription which immediately follows the marble in Dr Chandler's edition, N° xxiv. these very three letters are never so large as the rest, and often much smaller; of which

there are instances in the three first lines. See also Chronicle, two medals in the second part of Dorville's Sicula, Tab. xvi. Numb. 7. 9.

"From the archaisms, such as *εγ Λυκαρτίας, εγ Κυβελούς, εμ Παροι, &c. &c.* no conclusion can be drawn in favour of the authenticity of the inscription." Yet surely every thing common to it with other inscriptions, confessedly genuine, creates a reasonable presumption in its favour. "But what reason could there be for these archaisms in the Parian Chronicle? We do not usually find them in Greek writers of the same age, or even of a more early date." The reason is, according to our opinion, that such archaisms were then in use: this we know from other inscriptions, in which such archaisms (or, as our author afterward calls them, barbarisms) are frequent. Nothing can be inferred from the Greek writers, unless we had their autographs. The present system of orthography in our printed Greek books is out of the question. Again, "The inscription sometimes adopts and sometimes neglects these archaisms, as in lines 4, 12, 27, 52, 63, 67." This inconsistency either is no valid objection, or if it be valid, will demolish not only almost every other inscription, but almost every writing whatsoever. For example, in the inscription just quoted, N° xxiv. we find *τον βασιλια*, l. 20. and *σταμ, περιπλη*, 24. A little farther, N° xxvi. l. 31. we have *εΓ Μαγνησιας*, 57. 73. 81. *εΚ Μαγνησιας*, and 106. 108. *εΚΓ Μαγνησιας*. The Corcyrean inscription (Montfaucon, *Diar. Ital.* p. 420.) promiscuously uses *εΚδανιζομαι* and *εΓδανιζομαι*. In English, who is surprised to find *has* and *bath*, *a hand* and *an hand*, *a useful* and *an useful*, in the works of the same author? We could produce instances of this inaccuracy from the same page, nay from the same sentence.

"The authenticity of those inscriptions, in which these archaisms appear, must be established, before they can be produced in opposition to the present argument." This is, we cannot help thinking, rather too severe a restriction. If no inscription may be quoted before it be proved genuine, the learned author of the Dissertation need not be afraid of being confuted; for nobody will engage with him on such conditions. Perhaps the reverse of the rule will be thought more equitable; that every inscription be allowed to be genuine, till its authenticity be rendered doubtful by probable arguments. We will conclude this head with two short observations. In Selden's copy, l. 26. was written *ΠΟΗΣΙΝ*, which the later editors have altered to *ΠΟΙΗΣΙΝ*, but without reason, the other being the more ancient way of writing, common in MSS. and sometimes found on inscriptions. (See G. Koen's *Notes on Gregorius de Dialectis*, p. 30.) In l. 83. the marble has *Καλλίου*, for which Palmer wished to substitute *Καλλίου*. Dr Taylor refutes him from the *Marmor Sandvicense*, observing at the same time, that this orthography occurs in no other place whatever except in these two monuments. Is it likely that two engravers should by chance coincide in the same mistake, or that the forger of the Parian Chronicle (if it be forged) should have seen the *Marmor Sandvicense*, and taken notice of this peculiarity with the intention of afterward employing it in the fabrication of an imposture?

The

Chronicle.

The Reviewers next proceed to consider, but more briefly, the other objections.

II. *It is not probable that the Chronicle was engraved for private use.* 1. *Because it was such an expence, as few learned Greeks were able to afford.* If only a few were able to afford it, some one of those few might be willing to incur it. But let Mr R. consider how likely it is that a modern, and probably a needy Greek, should be more able to afford it in the last century, than a learned Greek 2000 years ago! 2. *A manuscript is more readily circulated.* Do men never prefer cumbrous splendor to cheapness and convenience? And if this composition, instead of being engraved on marble, had been committed to parchment, would it have had a better chance of coming down to the present age? Such a flying sheet would soon be lost; or, if a copy had, by miracle, been preserved to us, the objections to its being genuine would be more plausible than any that have been urged against the inscription. What Mr R. says about the errors to which an inscription is liable, &c. will only prove that chronological inscriptions ought not to be engraved; but not that they never were. We allow that the common method of writing in the reign of Ptolemy Philadelphus was not on stones. But it was common enough to occur to the mind of any person who wished to leave behind him a memorial at once of his learning and magnificence.

III. This objection, *that the marble does not appear to be engraved by public authority*, we shall readily admit, though Bentley (*Diff. on Phalaris*, p. 251.) leans to the contrary opinion. In explaining this objection, the learned dissertator observes, that though the expression, *ἀρχοντος ἐν Πάρῳ*, would lead us to suppose that the inscription related to Paros, not a single circumstance in the history of that island is mentioned. But this expression only shows that the author was an inhabitant of Paros, and intended to give his readers a clue, or *parapegma*, by the aid of which they might adjust the general chronology of Greece to the dates of their own history. "It is as absurd as would be a marble in Jamaica containing the revolutions of England." We see no absurdity in supposing a book to be written in Jamaica containing the revolutions of England. The natives of Paros were not uninterested in events relating to the general history of Greece, particularly of Athens; and how can we tell whether the author were an *inquilinus* or a native of the island; whether he thought it a place beneath his care; or whether he had devoted a separate inscription to the chronology of Paros?

IV. *It has been frequently observed, that the earlier periods of the Grecian history are involved in darkness and confusion.* Granted. It follows then, that "an author who should attempt to settle the dates of the earlier periods would frequently contradict preceding, and be contradicted by subsequent, writers: that he would naturally fall into mistakes; and at best could only hope to adopt the most probable system. But the difficulty of the task, or the impossibility of success, are not sufficient to prove that no man has been rash or mad enough to make the attempt." On the contrary, we know that many have made it. What a number of discordant opinions has Mr R. himself given us from the ancients concerning the age of Homer? This consideration will in part obviate another objection, that the Parian

Chronicle.

Chronicle does not agree with any ancient author. For if the ancients contradict one another, how could it follow more than one of them? and why might not the author, without any imputation of ignorance or rashness, sometimes depart from them all? If indeed he disagrees with them when they are unanimous, it might furnish matter for suspicion; though even this would be far from a decisive argument, unless the ancients were so extremely unlike the moderns, as never to be fond of singular and paradoxical positions.

V. *This Chronicle is not once mentioned by any writer of antiquity.* How many of those inscriptions, which are preserved to the present day, are mentioned by classical authors? Verrius Flaccus composed a Roman kalendar, which, as a monument of his learning and industry, was engraved on marble, and fixed in the most public part of Preneste. Fragments of this very kalendar were lately dug up at Preneste, and have been published by a learned Italian. Now, if the passage of Suetonius, which informs us of this circumstance, had been lost, would the silence of the Latin writers prove that the fragments were not genuine remains of antiquity? It may be said that the cases are not parallel; for not a single author mentions the Parian Chronicle, whereas Suetonius does mention Verrius's Roman kalendar. To this we answer, It is dangerous to deny the authenticity of any monument on the slender probability of its being casually mentioned by a single author. We shall also observe, that this fact of the Hemicyclium of Verrius will answer some part of the Dissertator's second objection: "The Parian Chronicle is not an inscription that might have been concealed in a private library." Why not? it is of no extraordinary bulk; and might formerly have been concealed in a private library, or in a private room, with as much ease as many inscriptions are now concealed in very narrow spaces. But unless this monument were placed in some conspicuous part of the island, and obtruded itself on the notice of every traveller, the wonder will in great measure cease why it is never quoted by the ancients. Of the nine authors named in p. 109, had any one ever visited Paros? If Pausanias had travelled thither, and published his description of the place, we might perhaps expect to find some mention of this marble in so curious and inquisitive a writer. But though the inscription existed, and were famous at Paros, there seems no necessity for any of the authors whose works are still extant to have known or recorded it. If there be, let this learned antagonist point out the place where this mention ought to have been made. If any persons were bound by a stronger obligation than others to speak of the Parian inscription, they must be the professed chronologers: but alas! we have not the entire works of so much as a single ancient chronologer: it is therefore impossible to determine whether this Chronicle were quoted by any ancient. And supposing it had been seen by some ancient, whose writings still remain, why should he make particular mention of it? Many authors, as we know from their remains, very freely copied their predecessors without naming them. Others, finding only a collection of bare events in the inscription, without historical proofs or reasons, might entirely neglect it, as deserving no credit. Mr R. seems to lay much stress on the precise, exact, and particular

spe-

Chronicle. specification of the events, p. 109. But he ought to reflect, that this abrupt and positive method of speaking is not only usual, but necessary, in such short systems of chronology as the marble contains, where events only, and their dates, are set down, unaccompanied by any examination of evidences for and against, without stating any computation of probabilities, or deduction of reasons. When therefore a chronological writer had undertaken to reduce the general history of Greece into a regular and consistent system, admitting that he was acquainted with this inscription, what grounds have we to believe that he would say any thing about it? Either his system coincided with the *Chronicle* or not: if it coincided, he would very probably disdain to prop his own opinions with the unsupported assertions of another man, who, as far as he knew, was not better informed than himself. On the other hand, if he differed from the authority of the marble, he might think it a superfluous exertion of complaisance, to refute, by formal demonstration, a writer who had chosen to give no reasons for his own opinion. We shall pass hence to

Objection VII. With respect to the parachronisms that Mr R. produces, we shall without hesitation grant, that the author of the inscription may have committed some mistakes in his chronology, as perhaps concerning Phidon, whom he seems to have confounded with another of the same name, &c. But these mistakes will not conclude against the antiquity of the inscription, unless we at the same time reject many of the principal Greek and Roman writers, who have been convicted of similar errors. We return therefore to

Objection VI. *Some of the facts seem to have been taken from authors of a later date.* We have endeavoured impartially to examine and compare the passages quoted in proof of this objection; but we are obliged to confess, that we do not perceive the faintest traces of theft or imitation. One example only deserves to be excepted; to which we shall therefore pay particular attention.

“The names of six; and, if the lacunæ are properly supplied, the names of twelve cities, appear to have been engraved on the marble, exactly as we find them in *Ælian's Various History*. But there is not any imaginable reason for this particular arrangement. It does not correspond with the time of their foundation, with their situation in Ionia, with their relative importance, or with the order in which they are placed by other eminent historians.”

The chance of six names, says Mr R. being placed by two authors in the same order, is as 1 to 720; of 12, as 1 to 479,001,600. “It is therefore utterly improbable that these names would have been placed in this order on the marble, if the author of the inscription had not transcribed them from the historian.”

On this argument we shall observe, 1. That the very contrary conclusion might possibly be just, that the historian transcribed from the inscription. Yet we shall grant that in the present case this is improbable, especially if the author of the *Various History* be the same *Ælian*, who, according to *Philostratus*, *Vit. Sophist.* II. 31. never quitted Italy in his life. But an intermediate writer might have copied the marble, and *Ælian* might have been indebted to him. 2dly, We

N^o 79.

Chronicle. see no reason to allow, that the lacunæ are properly supplied. Suppose we should assert, that the names stood originally thus: Miletus, Ephesus, Erythræ, Clazomenæ, Lebedos, Chios, Phocæa, Colophon, Myus, Priene, Samos, Teos. In this arrangement, only four names would be together in the same order with *Ælian*; and from these Miletus must be excepted, because there is an obvious reason for mentioning that city first. Three only will then remain; and surely that is too slight a resemblance to be construed into an imitation. For *Pausanias* and *Paterculus*, quoted by our author, p. 154, have both enumerated the same twelve cities, and both agree in placing the five last in the same order; nay, the six last, if *Vossius's* conjecture that TEUM ought to be inserted in *Paterculus* after Myum TEM be as true as it is plausible. But who imagines that *Pausanias* had either opportunity or inclination to copy *Paterculus*? 3dly, Allowing that the names were engraved on the marble exactly in the order that *Ælian* has chosen, is there no way of solving the phenomenon but by supposing that one borrowed from the other? Seven authors at least (Mr R. seems to say more, p. 154, 5.) mention the colonization of the same cities: how many authors now lost may we reasonably conjecture to have done the same? If therefore the composer of the *Chronicle* and *Ælian* lighted on the same author, the former would probably preserve the same arrangement that he found, because in transcribing a list of names, he could have no temptation to deviate; and the latter would certainly adhere faithfully to his original, because he is a notorious and servile plagiarist. Mr R. indeed thinks, p. 158, that if a succeeding writer had borrowed the words of the inscription, he would not have suppressed the name of the author. This opinion must fall to the ground, if it be shown that *Ælian* was accustomed to suppress the names of the authors to whom he was obliged. *Ælian* has given a list of fourteen celebrated gluttons; and, elsewhere, another of twenty-eight drunkards (from which, by the way, it appears, that people were apt to eat and drink rather too freely in ancient as well as modern times); and both these lists contain exactly the same names in the same order with *Athenæus*. Now it is observable, that fourteen names may be transposed 87,178,291,200 different ways, and that twenty-eight names admit of 304,888,344,611,713,860,501,504,000,000 different transpositions, &c. &c. *Ælian* therefore transcribed them from *Athenæus*? yet *Ælian* never mentions *Athenæus* in his *Various History*. So that whether *Ælian* copied from the marble, or only drew from a common source, he might, and very probably would, conceal his authority.

VIII. *The history of the discovery of the Marbles is obscure and unsatisfactory.*

In p. 169, it is said to be “related with suspicious circumstances, and without any of those clear and unequivocal evidences which always discriminate truth from falsehood.” The question then is finally decided. If the inscription has not any of those evidences which truth always possesses, and which falsehood always wants, it is most certainly forged. The learned dissertator seems for a moment to have forgotten the modest character of a doubter, and to personate the dogmatist. But waving this, we shall add, that, as far as we can see,

no

Chronicle. no appearance of fraud is discoverable in any part of the transaction. The history of many inscriptions is related in a manner equally unsatisfactory; and if it could be clearly proved that the marble was dug up at Paros, what would be easier for a critic, who is determined at any rate to object, than to say, that it was buried there in order to be afterward dug up? If the person who brought this treasure to light had been charged on the spot with forging it, or concurring in the forgery, and had then refused to produce the external evidences of its authenticity, we should have a right to question, or perhaps to deny, that it was genuine. But no such objection having been made or hinted, at the original time of its discovery, it is unreasonable to require such testimony as it is now impossible to obtain. "There is nothing said of it in Sir T. Roe's negotiations." What is the inference? That Sir Thomas knew nothing of it, or believed it to be spurious, or forged it, or was privy to the forgery? Surely nothing of this kind can be pretended. But let our author account for the circumstance if he can. To us it seems of no consequence on either side. "Peiresc made no effort to recover this precious relic; and from his composure he seems to have entertained some secret suspicions of its authenticity." Peiresc would have had no chance of recovering it after it was in the possession of Lord Arundel's agents. He was either a real or a pretended patron of letters; and it became him to affect to be pleased that the inscription had come into England, and was illustrated by his learned friend Selden. John F. Gronovius had, with great labour and expence, collated Anna Comnena's Alexiades, and intended to publish them. While he was waiting for some other collations, they were intercepted, and the work was published by another. As soon as Gronovius heard this unpleasant news, he answered, that learned men were engaged in a common cause; that if one prevented another in any publication, he ought rather to be thanked for lightening the burden, than blamed for interfering. But who would conclude from this answer, that Gronovius thought the Alexiades spurious, or not worthy of any regard?

Mr R. calculates, that the venders of the marble received 200 pieces. But here again we are left in the dark, unless we knew the precise value of these pieces. Perhaps they might be equal to an hundred of our pounds, perhaps only to fifty. Besides, as they at first bargained with Samson, Peiresc's supposed Jew agent, for fifty pieces only, they could not have forged the inscription with the clear prospect of receiving more; neither does it appear that they were paid by Samson. It is fully as reasonable to suppose fraud on the one side as on the other; and if Samson, after having the marble in his possession, refused or delayed to pay the sum stipulated, he might, in consequence of such refusal or delay, be thrown into prison, and might, in revenge, damage the marble before the owners could recover it. We own this account of ours to be a romance; but it is lawful to combat romance with romance.

IX. *The world has been frequently imposed upon by spurious books and inscriptions; and therefore we should be extremely cautious with regard to what we receive under the venerable name of antiquity.*

Vol. IV. Part II.

Much truth is observable in this remark. But the danger lies in applying such general apophthegms to particular cases. In the first place, it must be observed, that no forged books will exactly suit Mr R.'s purpose, but such as pretend to be the author's own hand-writing; nor any inscriptions, but such as are still extant on the original materials, or such as were known to be extant at the time of their pretended discovery. Let the argument be bounded by these limits, and the number of forgeries will be very much reduced. We are not in possession of Cyriacus Anconitanus's book; but if we were governed by authority, we should think that the testimony of Reinesius in his favour greatly overbalances all that Augustinus has said to his prejudice. The opinion of Reinesius is of the more weight, because he suspects Urfinus of publishing counterfeit monuments. We likewise find the most eminent critics of the present age quoting Cyriacus without suspicion (*Vid. Ruhnken. in Timæi Lex. Plat. p. 10. apud Koen, ad Gregor. p. 140.*) The doctrine advanced in the citation from Hardouin is exactly conformable to that writer's usual paradoxes. He wanted to destroy the credit of all the Greek and Latin writers. But inscriptions hung like a millstone about the neck of his project. He therefore resolved to make sure work, and to deny the genuineness of as many as he saw convenient: to effect which purpose, he intrenches himself in a general accusation. If the author of the dissertation had quoted a few more paragraphs from Hardouin, in which he endeavours, after his manner, to show the forgery of some inscriptions, he would at once have administered the poison and the antidote. But to the reveries of that learned madman, respecting Greek supposititious compositions of this nature, we shall content ourselves with opposing the sentiments of a modern critic, whose judgment on the subject of spurious inscriptions will not be disputed. Maffei, in the introduction to the third book, c. 1. p. 51. of his admirable, though unfinished, work *de Arte Critica Lapidaria*, uses these words: *Inscriptionum Græce loquentium commentitias, si cum Latinis comparemus, deprehendi paucas; neque enim ullum omnino est, in tanta debacchantium falsariorum libidine, monumenti genus, in quod ii sibi minus licere putaverint. Argumento est, paucissimas usque in hanc diem ab eruditis viris, et in hoc literarum genere plurimum versatis rejectas esse, falsique damnatas.*

Books of CHRONICLES, a canonical writing of the Old Testament. It is uncertain which were written first, *The Books of Kings*, or *The Chronicles*, since they each refer to the other. However it be, the latter is often more full and comprehensive than the former. Whence the Greek interpreters call these two books Παλαιπομένα, *Supplements, Additions*, because they contain some circumstances which are omitted in the other historical books. The Jews make but one book of the Chronicles, under the title of *Dibre-Haiamim*, i. e. *Journals or Annals*. Ezra is generally believed to be the author of these books. It is certain they were written after the end of the Babylonish captivity and the first year of the reign of Cyrus, of whom mention is made in the last chapter of the second book.

The *Chronicles*, or *Paraleipomena*, are an abridgement

Chronicles,

logy.

ment of all the sacred history, from the beginning of the Jewish nation to their first return from the captivity, taken out of those books of the Bible which we still have, and out of other annals which the author had then by him. The design of the writer was to give the Jews a series of their history. The first book relates to the rise and propagation of the people of Israel from Adam, and gives a punctual and exact account of the reign of David. The second book sets

down the progress and end of the kingdom of Judah, to the very year of their return from the Babylonish captivity.

logy.

CHRONOGRAM, a species of false wit, consisting in this, that a certain date or epocha is expressed by numeral letters of one or more verses; such is that which makes the motto of a medal struck by Gustavus Adolphus in 1632:

ChristVs. DVX; ergo trIVMphVs.

C H R O N O L O G Y,

TREATS of time, the method of measuring its parts, and adapting these, when distinguished by proper marks and characters, to past transactions, for the illustration of history. This science therefore consists of two parts. The first treats of the proper measurement of time, and the adjustment of its several divisions; the second, of fixing the dates of the various events recorded in history, and ranging them, according to the several divisions of time, in the order in which they happened.

cients.

Inaccurate
methods of
computing
time at first
made use
of.

Chronology, comparatively speaking, is but of modern date. The ancient poets appear to have been entirely unacquainted with it; and Homer, the most celebrated of them all, mentions nothing like a formal kalendar in any part of his writings. In the most early periods, the only measurement of time was by the seasons, the revolutions of the sun and moon; and many ages must have elapsed before the mode of computation by dating events came into general use. Several centuries intervened between the era of the olympic games and the first historians; and several more between these and the first authors of chronology. When time first began to be reckoned, we find its measures very indeterminate. The succession of Juno's priestesses at Argos served Hellanicus for the regulation of his narrative; while Ephorus reckoned his matters by generations. Even in the histories of Herodotus and Thucydides, we find no regular dates for the events recorded; nor was there any attempt to establish a fixed era, until the time of Ptolemy Philadelphus, who attempted it by comparing and correcting the dates of the olympiads, the kings of Sparta, and the succession of the priestesses of Juno at Argos. Eratosthenes and Apollodorus digested the events recorded by them according to the succession of the olympiads and of the Spartan kings.

The uncertainty of the measures of time in the most early periods renders the histories of those times equally uncertain; and even after the invention of dates and eras, we find the ancient historians very inattentive to them, and inaccurate in their computations. Frequently their eras and years were reckoned differently without their being sensible of it, or at least without giving the reader any information concerning it; a circumstance which has rendered the fragments of their works now remaining of very little use to posterity. The Chaldean and Egyptian writers are generally acknowledged to be fabulous; and Strabo acquaints us, that Diodorus Siculus, and the other early

historians of Greece, were ill informed and credulous. Hence the disagreement among the ancient historians, and the extreme confusion and contradiction we meet with on comparing their works. Hellanicus and Acusilaus disagreed about their genealogies; the latter rejected the traditions of Hesiod. Timæus accused Ephorus of falsehood, and the rest of the world accused Timæus. The most fabulous legends were imposed on the world by Herodotus; and even Thucydides and Diodorus, generally accounted able historians, have been convicted of error. The chronology of the Latins is still more uncertain. The records of the Romans were destroyed by the Gauls; and Fabius Pictor, the most ancient of their historians, was obliged to borrow the greatest part of his information from the Greeks. In other European nations the chronology is still more imperfect and of a later date; and even in modern times, a considerable degree of confusion and inaccuracy has arisen from want of attention in the historians to ascertain the dates and epochs with precision.

Ancient hi-
storians not
to be cre-
dited.

From these observations it is obvious how necessary a proper system of chronology must be for the right understanding of history, and likewise how very difficult it must be to establish such a system. In this, however, several learned men have excelled, particularly Julius Africanus, Eusebius of Cæsarea, George Cyncelle, John of Antioch, Dennis, Petau, Cluvier, Calvisius, Usher, Simson Marsham, Blair, and Playfair. It is founded, 1. On astronomical observations, particularly of the eclipses of the sun and moon, combined with the calculations of the eras and years of different nations. 2. The testimonies of credible authors. 3. Those epochs in history which are so well attested and determined, that they have never been controverted. 4. Ancient medals, coins, monuments, and inscriptions. None of these, however, can be sufficiently intelligible without an explanation of the first part, which, we have already observed, considers the divisions of time, and of which therefore we shall treat in the first place.

Utility of
chronology,
list of chro-
nologists,
&c.

The most obvious division of time is derived from the apparent revolutions of the celestial bodies, particularly of the sun, which by the vicissitudes of day and night becomes evident to the most barbarous and ignorant nations. In strict propriety of speech the word *day* signifies only that portion of time during which the sun diffuses light on any part of the earth; but in the most comprehensible sense, it includes the night also, and is called by chronologers a *civil day*; by astronomers a *natural*, and sometimes an *artificial*, day.

Of the di-
vision of
time into
days.

By

7
Civil, solar
&c. days
defined.

By a civil day is meant the interval betwixt the sun's departure from any given point in the heavens and next return to the same, with as much more as answers to its diurnal motion eastward, which is at the rate of 59 minutes and 8 seconds of a degree, or 3 minutes and 57 seconds of time. It is also called a *solar* day, and is longer than a *sidereal* one, inasmuch that, if the former be divided into 24 equal parts or hours, the latter will consist only of 23 hours 56 minutes. The apparent inequality of the sun's motion, likewise, arising from the obliquity of the ecliptic, produces another inequality in the length of the days: and hence the difference betwixt real and apparent time, so that the apparent motion of the sun cannot always be a true measure of duration. Those inequalities, however, are capable of being reduced to a general standard, which furnishes an exact measure throughout the year; whence arises the difference between mean and apparent time, as is explained under the article ASTRONOMY.

8
Different
ways of
computing
the begin-
ning of the
day.

There have been very considerable differences among nations with regard to the beginning and ending of their days. The beginning of the day was counted from sunrise by the Babylonians, Syrians, Persians, and Indians. The civil day of the Jews was begun from sunrise, and their sacred one from sunset; the latter mode of computation being followed by the Athenians, Arabs, ancient Gauls, and other European nations. According to some, the Egyptians began their day at sunset, while others are of opinion that they computed from noon or from sunrise; and Pliny informs us that they computed their civil day from one midnight to another. It is probable, however, that they had different modes of computation in different provinces or cities. The Ausonians, the most ancient inhabitants of Italy, computed the day from midnight; and the astronomers of Cathay and Oighur in the East Indies reckoned in the same manner. This mode of computation was adopted by Hipparchus, Copernicus, and other astronomers, and is now in common use among ourselves. The *astronomical* day, however, as it is called, on account of its being used in astronomical calculations, commences at noon, and ends at the same time the following day. The Mahometans reckon from one twilight to another. In Italy, the civil day commences at some indeterminate point after sunset; whence the time of noon varies with the season of the year. At the summer solstice, the clock strikes 16 at noon, and 19 at the time of the winter solstice. Thus also the length of each day differs by several minutes from that immediately preceding or following it. This variation requires a considerable difficulty in adjusting their time by clocks. It is accomplished, however, by a sudden movement which corrects the difference when it amounts to a quarter of an hour; and this it does sometimes at the end of eight days, sometimes at the end of 15, and sometimes at the end of 40. Information of all this is given by a printed kalendar, which announces, that from the 16th of February, for instance, to the 24th, it will be noon at a quarter past 18; from the 24th of February to the 6th of March, it will be noon at 18 o'clock precisely; from the first of June to the 13th of July, the hour of noon will be at 16 o'clock; on the 13th of July it

will be at half an hour after 16; and so on throughout the different months of the year. This absurd method of measuring the day continues, notwithstanding several attempts to suppress it, throughout the whole of Italy, a few provinces only excepted.

The subdivisions of the day have not been less various than the computations of the day itself. The most obvious division, and which could at no time, nor in no age, be mistaken, was that of morning and evening. In process of time the two intermediate points of noon and midnight were determined; and this division into quarters was in use long before the invention of hours.

From this subdivision probably arose the method used by the Jews and Romans of dividing the day and night into four vigils or watches. The first began at sun-rising, or six in the morning; the second at nine; the third at twelve; and the fourth at three in the afternoon. In like manner the night was divided into four parts; the first beginning at six in the evening, the second at nine, the third at twelve, and the fourth at three in the morning. The first of these divisions was called by the Jews the *third* hour of the day; the second the *sixth*; the third the *ninth*; and the fourth the *twelfth*, and sometimes the *eleventh*. Another division in use, not only among the nations above mentioned, but the Greeks also, was that which reckoned the first quarter from sunset to midnight; the second from midnight to sunrise; the third, or morning watch, from morning to noon; and the fourth from noon to sunset.

It is uncertain at what time the more minute subdivision of the day into hours first commenced. It does not appear from the writings of Moses that he was acquainted with it, as he mentions only the morning, mid-day, evening, and sunset. Hence we may conclude, that the Egyptians at that time knew nothing of it, as Moses was well skilled in their learning. According to Herodotus, the Greeks received the knowledge of the twelve hours of the day from the Babylonians. It is probable, however, that the division was actually known and in use before the name *hour* was applied to it; as Censorinus informs us that the term was not made use of in Rome for 300 years after its foundation; nor was it known at the time the twelve tables were constructed.

The eastern nations divide the day and night in a very singular manner; the origin of which is not easily discovered. The Chinese have five watches in the night, which are announced by a certain number of strokes on a bell or drum. They begin by giving one stroke, which is answered by another; and this is repeated at the distance of a minute or two, until the second watch begin, which is announced by two strokes; and so on throughout the rest of the watches. By the ancient Tartars, Indians, and Persians, the day was divided into eight parts, each of which contained seven hours and a half. The Indians on the coast of Malabar divide the day into six parts, called *najika*; each of these six parts is subdivided into 60 others, called *venaigas*; the *venaiga* into 60 *birpes*; the *birpe* into 10 *kenikans*; the *kenikan* into four *mattires*; the *mattire* into eight *kannimas* or *caignodes*; which divisions, according to our mode of computation, stand as follows.

10

Najika, Venaiga, Birpe, Kenikan, Mattire, Caignode.
 24 min. 24 sec. 4 sec. $\frac{2}{3}$ sec. $\frac{1}{10}$ sec. $\frac{1}{100}$ sec.

The day of the Chinese is begun at midnight, and ends with the midnight following. It is divided into twelve hours, each distinguished by a particular name and figure. They also divide the natural day into 100 parts, and each of these into 100 minutes; so that the whole contains 10,000 minutes. In the northern parts of Europe, where only two seasons are reckoned in the year, the divisions of the day and night are considerably larger than with us. In Iceland the 24 hours are divided into eight parts; the first of which commences at three in the morning; the second at five; the third at half an hour after eight; the fourth at eleven; the fifth at three in the afternoon; the sixth at six in the evening; the seventh at eight, and the last at midnight. In the eastern part of Turkestan, the day is divided into twelve equal parts, each of which is distinguished by the name of some animal. These are subdivided into eight *keh*; so that the whole 24 hours contain 96 *keh*.

¹³
 Divisions
 of the hour
 into mi-
 nutes, &c.

The modern divisions of the hour in use among us are into minutes, seconds, thirds, fourths, &c. each being a sixtieth part of the former subdivision. By the Chaldeans, Jews, and Arabians, the hour is divided into 1080 scruples; so that one hour contains 60 minutes, and one minute, 18 scruples. The ancient Persians and Arabs were likewise acquainted with this division; but the Jews are so fond of it, that they pretend to have received it in a supernatural manner. "Issachar (say they) ascended into heaven, and brought from thence 1080 parts for the benefit of the nation."

¹⁴
 Methods of
 announcing
 the hours.

The division of the day being ascertained, it soon became an object to indicate in a public manner the expiration of any particular hour or division; as without some general knowledge of this kind, it would be in a great measure impossible to carry on business. The methods of announcing this have been likewise very different. Among the Egyptians it was customary for the priests to proclaim the hours like watchmen among us. The same method was followed at Rome; nor was there any other method of knowing the hours until the year 293 B. C. when Papirius Cursor first set up a sun-dial in the Capitol. A similar method is practised among the Turks, whose priests proclaim from the top of their mosques, the cock-crowing, day-break, mid-day, three o'clock in the afternoon, and twilight, being their appointed times of worship.

¹⁵
 Invention
 of instru-
 ments for
 this pur-
 pose,

As this mode of proclaiming the hour could not but be very inconvenient, as well as imperfect, the introduction of an instrument which every one could have in his possession, and which might answer the same purpose, must have been considered as a valuable acquisition. One of the first of these was the clepsydra or water clock*. Various kinds of these were in use among the Egyptians at a very early period. The invention of the instrument is attributed to Thoth or Mercury, and it was afterwards improved by Ctesibius of Alexandria. It was a common measure of time among the Greeks, Indians, and Chaldeans, as well as the Egyptians, but was not introduced into Rome till the time of Scipio Nasica. The Chinese astronomers

have long made use of it; and by its means divided the zodiac into twelve parts; but it is a very inaccurate measure of time, varying, not only according to the quantity of water in the vessel, but according to the state of the atmosphere.

The clepsydra was succeeded by the gnomon or sun-dial.—This, at first, was no more than a stile erected perpendicularly to the horizon; and it was a long time before the principles of it came to be thoroughly understood. The invention is with great probability attributed to the Babylonians, from whom the Jews received it before the time of Ahaz, when we know that a sun-dial was already erected at Jerusalem. The Chinese and Egyptians also were acquainted with the use of the dial at a very early period, and it was considerably improved by Anaximander or Anaximenes; one of whom is for that reason looked upon to be the inventor. Various kinds of dials, however, were invented and made use of in different nations long before their introduction at Rome. The first erected in that city, as has been already mentioned, was that by Papirius Cursor; and 30 years after, Valerius Missala brought one from Sicily, which was used in Rome for no less than 99 years, though constructed for a Sicilian latitude, and consequently incapable of showing the hours exactly in any other place; but at last another was constructed by L. Philippus, capable of measuring time with greater accuracy.

It was long after the invention of dials before mankind began to form any idea of clocks; nor is it well known at what period they were first invented. A clock was sent by Pope Paul I. to Pepin king of France, which at that time was supposed to be the only one in the world. A very curious one was also sent to Charles the Great from the khalif Haroun Al-raschid, which the historians of the time speak of with surprise and admiration: but the greatest improvement was that of Mr Huygens, who added the pendulum to it. Still, however, the instruments for dividing time were found to be inaccurate for nice purposes. The expansion of the materials by heat, and their contraction by cold, would cause a very perceptible alteration in the going of an instrument in the same place at different times of the year, and much more if carried from one climate to another. Various methods have been contrived to correct this; which indeed can be done very effectually at land by a certain construction of the pendulum; but at sea, where a pendulum cannot be used, the inaccuracy is of consequence much greater: nor was it thought possible to correct the errors arising from these causes in any tolerable degree, until the late invention of Mr Harrison's time-piece, which may be considered as making perhaps as near an approach to perfection as possible.

Having thus given an account of the more minute divisions of time, with the methods of measuring them, we must now proceed to the larger; which more properly belong to chronology, and which must be kept on record, as no instrument can be made to point them out. Of these the division into weeks of seven days is one of the most ancient, and probably took place from the creation of the world. Some, indeed, are of opinion, that the week was invented

* See Clepsydra.

some time after for the more convenient notation of time; but whatever may be in this, we are certain that it is of the highest antiquity, and even the most rude and barbarous nations have made use of it. It is singular indeed that the Greeks, notwithstanding their learning, should have been ignorant of this division; and M. Goguet informs us, that they were almost the only nation who were so. By them the month of 30 days was divided into three times 10, and the days of it named accordingly. Thus the 15th day of the month was called the *second fifth*, or fifth of the second tenth; the 24th was called the *third fourth*, or the fourth day of the third tenth. This method was in use in the days of Hesiod, and it was not until several ages had elapsed, that the use of weeks was received into Greece from the Egyptians. The inhabitants of Cathay, in the northern part of China, were likewise unacquainted with the week of seven days, but divided the year into six parts of 60 days each. They had also a cycle of 15 days, which they used as a week. The week was likewise unknown to the ancient Persians and to the Mexicans; the former having a different name for every day of the month, and the latter making use of a cycle of 13 days. By almost all other nations the week of seven days was adopted.

16
Of holidays.

It is remarkable, that one day in the week has always been accounted as sacred by every nation. Thus Saturday was consecrated to pious purposes among the Jews, Friday by the Turks, Tuesday by the Africans of Guinea, and Sunday by the Christians. Hence also the origin of *Feria* or holidays, frequently made use of in Systems of Chronology; and which arose from the following circumstance. In the church of Rome the old ecclesiastical year began with Easter-week; all the days of which were called *Feria* or *Feriat*, that is, holy, or sacred days; and in process of time the days of other weeks came to be distinguished by the same appellation, for the two following reasons, 1. Because every day ought to be holy in the estimation of a Christian. 2. Because all days are holy to ecclesiastics, whose time ought to be entirely devoted to religious worship.—The term *week* is sometimes used to signify seven years, not only in the prophetic writings, but likewise by profane authors; thus Varro, in his book inscribed *Hebdomades*, informs us, that he had then entered the 12th week of his years.

17
Of months.

The next division of time superior to weeks, is that of *months*. This appears to have been, if not coeval with the creation, at least in use before the flood. As this division is naturally pointed out by the revolution of the moon, the months of all nations were originally lunar; until after some considerable advances had been made in science, the revolutions of that luminary were compared with the sun, and thus the limits of the month fixed with greater accuracy. The division of the year into 12 months, as being founded on the number of full revolutions of the moon in that time, has also been very general; though Sir John Chardin informs us, that the Persians divided the year into 24 months; and the Mexicans into 18 months of 20 days each. The months generally contained 30 days, or 29 and 30 days alternately; though this rule was far from being without exception. The months

of the Latins consisted of 16, 18, 22, or 36 days; and Romulus gave his people a year of 10 months and 304 days. The Kamtschadales divide the year into 10 months; reckoning the time proper for labour to be nine months, and the winter season, when they are obliged to remain inactive, only as one month.

It has been a very ancient custom to give names to the different months of the year, though this appears to have been more modern than the departure of the Israelites out of Egypt, as they would otherwise undoubtedly have carried it with them; but for a considerable time after their settlement in Canaan, they distinguished the months only by the names of first, second, &c. After their return from the Babylonish captivity, they adopted the names given to the months by the Chaldeans. Other nations adopted various names, and arranged the months themselves according to their fancy. From this last circumstance arises the variety in the dates of the months; for as the year has been reckoned from different signs in the ecliptic, neither the number nor the quantity of months have been the same, and their situation has likewise been altered by the intercalations necessary to be made.

These intercalations became necessary on account of the excess of the solar above the lunar year; and the months composed of intercalary days are likewise called *embolismal*. These embolismal months are either *natural* or *civil*. By the former, the solar and lunar years are adjusted to one another; and the latter arises from the defect of the civil year itself. The *ador* of the Jews, which always consists of 30 days, is an example of the natural embolismal month.

The Romans had a method of dividing their months into kalends, nones, and ides. The first was derived from an old word *calo*, "to call"; because, at every new moon, one of the lower class of priests assembled the people, and called over, or announced, as many days as intervened betwixt that and the nones, in order to notify the difference of times and the return of festivals. The 2d, 3d, 4th, 5th, 6th, and 7th of March, May, July, and October, were the nones of these months; but in the other months were the 2d, 3d, 4th, and 5th days only. Thus the 5th of January was its nones; the 4th was *pridie nonarum*; the third, *tertio nonarum*, &c. The ides contained eight days in every month, and were nine days distant from the nones. Thus the 15th day of the four months already mentioned was the ides of them; but in the others the 13th was accounted as such; the 12th was *pridie iduum*, and the 11th *tertio iduum*. The ides were succeeded by the kalends; the 14th of January, for instance, being the 19th kalend of February; the 15th was the 18th kalend; and so on till the 31st of January, which was *pridie kalendarum*; and February 1st was the kalends.

18

Among the European nations the month is either astronomical or civil. The former are measured by the motion of the heavenly bodies; the civil consists of a certain number of days specified by the laws, or by the civil institutions of any nation or society. The astronomical months, being for the most part regulated by the motions of the sun and moon, are thus divided into solar and lunar, of which the former is sometimes also called *civil*. The astronomical solar month is the time

time which the sun takes up in passing through a sign of the ecliptic. The lunar month is periodical, synodical, sidereal, and civil. The synodical lunar month is the time that passes between any conjunction of the moon with the sun and the conjunction following. It includes the motion of the sun eastward during that time; so that a mean lunation consists of 29d. 12h. 44' 2" 8921. The sidereal lunar month is the time of the mean revolution of the moon with regard to the fixed stars. As the equinoctial points go backwards about 4" in the space of a lunar month, the moon must, in consequence of this retrocession, arrive at the equinox sooner than at any fixed star, and consequently the mean sidereal revolution must be longer than the mean periodical one. The latter consists of 27d. 7h. 43' 4" 6840. The civil lunar month is computed from the moon, to answer the ordinary purposes of life; and as it would have been inconvenient, in the computation of lunar months, to have reckoned odd parts of days, they have been composed of 30 days, or of 29 and 30 alternately, as the nearest round numbers. When the month is reckoned from the first appearance of the moon after her conjunction, it is called the *month of illumination*. The Arabs, Turks, and other nations, who use the era of the Hegira, follow this method of computation. As twelve lunar months, however, are 11 days less than a solar year, Julius Caesar ordained that the month should be reckoned from the course of the sun, and not of the moon; and that they should consist of 30 and 31 days alternately, February only excepted, which was to consist of 28 days commonly, and of 29 in leap-years.

19
Of years.

The highest natural division of time is into years. At first, however, it is probable that the course of the sun through the ecliptic would not be observed, but that all nations would measure their time by the revolutions of the moon. We are certain, at least, that the Egyptian year consisted originally of a single lunation; though at length it included two or three months, and was determined by the stated returns of the seasons. As the eastern nations, however, particularly the Egyptians, Chaldeans, and Indians, applied themselves in very early periods to astronomy, they found, by comparing the motions of the sun and moon together, that one revolution of the former included nearly 12 of the latter. Hence a year of 12 lunations was formed, in every one of which were reckoned 30 days; and hence also the division of the ecliptic into 360 degrees. The lunisolar year, consisting of 360 days, was in use long before any regular intercalations were made; and historians inform us, that the year of all ancient nations was lunisolar. Herodotus relates, that the Egyptians first divided the year into 12 parts by the assistance of the stars, and that every part consisted of 30 days. The Thebans corrected this year by adding five intercalary days to it. The old Chaldean year was also reformed by the Medes and Persians; and some of the Chinese missionaries have informed us, that the lunisolar year was also corrected in China; and that the solar year was ascertained in that country to very considerable exactness. The Latin year, before Numa's correction of it, consisted of 360 days, of which 304 were divided into ten months; to which were added two private months not mentioned in the kalendar.

The imperfection of this method of computing time is now very evident. The lunisolar year was about $5\frac{1}{4}$ days shorter than the true solar year, and as much longer than the lunar. Hence the months could not long correspond with the seasons; and even in so short a time as 34 years, the winter months would have changed places with those of summer. From this rapid variation, Mr Playfair takes notice that a passage in Herodotus, by which the learned have been exceedingly puzzled, may receive a satisfactory solution, viz. that "in the time of the ancient Egyptian kings, the sun had twice arisen in the place where it had formerly set, and twice set where it had arisen." By this he supposes it is meant, "that the beginning of the year had twice gone through all the signs of the ecliptic; and that the sun had risen and set twice in every day and month of the year." This, which some have taken for a proof of most extravagant antiquity, he further observes, might have happened in 138 years only; as in that period there would be a difference of nearly two years between the solar and lunar year. Such evident imperfections could not but produce a reformation every where; and accordingly we find that there was no nation which did not adopt the method of adding a few intercalary days at certain intervals. We are ignorant, however, of the person who was the first inventor of this method. The Theban priests attributed the invention to Mercury or Thoth; and it is certain that they were acquainted with the year of 365 days at a very early period. The length of the solar year was represented by the celebrated golden circle of Olymandyas of 365 cubits circumference; and on every cubit of which was inscribed a day of the year, together with the heliacal risings and settings of the stars. The monarch is supposed to have reigned in the 11th or 13th century before the Christian era.

20
Explanation of a passage in Herodotus.

The Egyptian solar year being almost six hours shorter than the true one, this inaccuracy, in process of time, produced another revolution; some circumstances attending which serve to fix the date of the discovery of the length of the year, and which from the above description of the golden circle, we may suppose to have been made during the reign of Olymandyas. The inundation of the Nile was annually announced by the heliacal rising of Sirius, to which the reformers of the kalendar adjusted the beginning of the year, supposing that it would remain immovable. In a number of years, however, it appeared that their suppositions in this were ill-founded. By reason of the inequality above mentioned, the heliacal rising of Sirius gradually advanced nearly at the rate of one day in four years; so that in 1461 years it completed a revolution, by arising on every succeeding day of the year, and returning to the point originally fixed for the beginning of the year. This period, equal to 1460 Julian years, was termed the *great Egyptian year*, or *canicular cycle*. From the accounts we have of the time that the canicular cycle was renewed, the time of its original commencement may be gathered with tolerable certainty. This happened, according to Censorinus, in the 138th year of the Christian æra. Reckoning backward therefore from this time for 1460 years, we come to the year B. C. 1322, when the sun was in Cancer, about 14 or 15 days after the summer solstice,

21
Great Egyptian year, or canicular cycle.

21
Of the time when it commenced.

solstice, which happened on July 5th. The Egyptians used no intercalation till the time of Augustus, when the corrected Julian year was received at Alexandria by his order; but even this order was obeyed only by the Greeks and Romans who resided in that city; the superstitious natives refusing to make any addition to the length of a year which had been so long established among them.

22
Uncertainty of the time when the true solar year was discovered.

We are not informed at what precise period the true year was observed to consist of nearly six hours more than the 365 days. Though the priests of Thebes claim the merit of the discovery, Herodotus makes no mention of it; neither did Thales, who introduced the year of 365 days into Greece, ever use any intercalation. Plato and Eudoxus are said to have obtained it as a secret from the Egyptians about 80 years after Herodotus, and to have carried it into Greece; which showed, that the knowledge of this form of the year was at that time recent, and only known to a few learned men.

23
Years of the Jews, &c.

The year of the ancient Jews was lunisolar; and we are informed by tradition, that Abraham preserved in his family, and transmitted to posterity, the Chaldean form of the year, consisting of 360 days; which remained the same without any correction until the date of the era of Nabonassar. The solar year was adopted among them after their return from the Babylonish captivity; but when subjected to the successors of Alexander in Syria, they were obliged to admit the lunar year into their kalendar. In order to adjust this year to the course of the sun, they added at certain periods a month to Adar, formerly mentioned, and called it *Ve Adar*. They composed also a cycle of 19 years, in seven of which they inserted the intercalary month. This correction was intended to regulate the months in such a manner, as to bring the 15th of Nisan to the equinoctial point; and likewise the courses of the seasons and feasts in such a manner, that the corn might be ripe at the passover as the law required.

24
Reformation of the kalendar by Julius Cæsar and pope Gregory.

We shall not take up the reader's time with any further account of the years made use of by different nations, all of which are resolved at last into the lunisolar; it will be sufficient to mention the improvements in the kalendar made by the two great reformers of it, Julius Cæsar, and Pope Gregory XIII. The institution of the Roman year by Romulus has been already taken notice of; but as this was evidently very imperfect, Numa, on his advancement to the throne, undertook to reform it. With a design to make a complete lunar year of it, he added 50 days to the 304 of Romulus; and from every one of his months, which consisted of 31 and 30 days, he borrowed one day. Of these additional days he composed two months; calling the one January, and the other February. Various other corrections and adjustments were made; but when Julius Cæsar obtained the sovereignty of Rome, he found that the months had considerably receded from the seasons to which Numa had adjusted them. To bring them forward to their places, he formed a year of 15 months, or 445 days; which, on account of its length, and the design with which it was formed, has been called the *year of confusion*. It terminated on the first of January 45 B. C. and from this period the civil year and months were re-

gulated by the course of the sun. The year of Numa being ten days shorter than the solar year, two days were added by Julius to every one of the months of January, August, and December; and one to April, June, September, and November. He ordained likewise, that an intercalary day should be added every fourth year to the month of February, by reckoning the 24th day, or sixth of the kalends of March, twice over. Hence this year was styled *bissextile*, and also *leap year*, from its leaping a day more than a common year.

The Julian year has been used by modern chronologers, as being a measure of time extremely simple and sufficiently accurate. It is still, however, somewhat imperfect; for as the true solar year consists of 365 d. 5 h. 48' 45 $\frac{1}{2}$ ", it appears that in 131 years after the Julian correction, the sun must have arrived one day too soon at the equinoctial point. During Cæsar's reign the vernal equinox had been observed by Soligenes on the 25th of March; but by the time of the Nicene council it had gone backward to the 21st. The cause of the error was not then known; but in 1582, when the equinox happened on the 11th of March, it was thought proper to give the kalendar its last correction. Pope Gregory XIII. having invited to Rome a considerable number of mathematicians and astronomers, employed ten years in the examination of their several formulæ, and at last gave the preference to that of Aloisia and Antoninus Lelius, who were brothers. Ten days were now cut off in the month of October, and the 4th of that month was reckoned the 15th. To prevent the seasons from receding in time to come, he ordained that one day should be added every fourth or bissextile year as before; and that the 1600th year of the Christian era, and every fourth century thereafter, should be a bissextile or leap year. One day therefore is to be intercalated in the years 2000, 2400, 2800, &c. but in the other centuries, as 1700, 1800, 1900, 2100, &c. it is to be suppressed, and these are to be reckoned as common years. Even this correction, however, is not absolutely exact; but the error must be very inconsiderable, and scarce amounting to a day and an half in 5000 years.

25
The commencement of the year has been determined by the date of some memorable event or occurrence, such as the creation of the world, the universal deluge, a conjunction of planets, the incarnation of our Saviour, &c. and of course has been referred to different points in the ecliptic. The Chaldean and the Egyptian years were dated from the autumnal equinox. The ecclesiastical year of the Jews began in the spring; but, in civil affairs, they retained the epoch of the Egyptian year. The ancient Chinese reckoned from the new moon nearest to the middle of Aquarius; but, according to some recent accounts, the beginning of their year was transferred (B. C. 1740) to the new moon nearest to the winter solstice. This likewise is the date of the Japanese year. Diemschid, or Gem-schid, king of Persia, observed, on the day of his public entry into Persepolis, that the sun entered into Aries. In commemoration of this fortunate event and coincidence, he ordained the beginning of the year to be removed from the autumnal to the vernal equinox. This epoch was denominated *Neuruz*, viz. new-day; and is still celebrated with great pomp and festivity.

(See EPOCHS). The ancient Swedish year commenced at the winter solstice, or rather at the time of the sun's appearance in the horizon, after an absence of about 40 days. The feast of this epoch was solemnised on the 20th day after the solstice. Some of the Grecian states computed from the vernal, some from the autumnal equinox, and others from the summer tropic. The year of Romulus commenced in March, and that of Numa in January. The Turks and Arabs date the year from the 16th of July; and the American Indians reckon from the first appearance of the new moon of the vernal equinox. The church of Rome has fixed new-year's-day on the Sunday that corresponds with the full moon of the same season. The Venetians, Florentines, and Pisans in Italy, and the inhabitants of Treves in Germany, begin the year at the vernal equinox. The ancient clergy reckoned from the 25th of March; and this method was observed in Britain, until the introduction of the new style (A. D. 1752); after which our year commenced on the 1st day of January.

26
Of cycles.

Besides these natural divisions of time arising immediately from the revolutions of the heavenly bodies, there are others formed from some of the less obvious consequences of these revolutions, which are called *cycles*, from the Greek *κυκλος*, a circle. The most remarkable of these are the following.

1. The *cycle of the sun* is a revolution of 28 years, in which time the days of the months return again to the same days of the week; the sun's place to the same signs and degrees of the ecliptic on the same months and days, so as not to differ one degree in 100 years; and the leap-years begin the same course over again with respect to the days of the week on which the days of the months fall. The *cycle of the moon*, commonly called the *golden number*, is a revolution of 19 years; in which time, the conjunctions, oppositions, and other aspects of the moon, are within an hour and half of being the same as they were on the same days of the months 19 years before. The *indiction* is a revolution of 15 years, used only by the Romans for indicating the times of certain payments made by the subjects to the republic: It was established by Constantine, A. D. 312.

27
Golden number.

28
To find the year of any cycle.

The year of our Saviour's birth, according to the vulgar era, was the 9th year of the solar cycle, the first year of the lunar cycle; and the 312th year after his birth was the first year of the Roman indiction. Therefore, to find the year of the solar cycle, add 9 to any given year of Christ, and divide the sum by 28, the quotient is the number of cycles elapsed since his birth, and the remainder is the cycle for the given year: If nothing remains, the cycle is 28. To find the lunar cycle, add one to the given year of Christ, and divide the sum by 19; the quotient is the number of cycles elapsed in the interval, and the remainder is the cycle for the given year: If nothing remains, the cycle is 19. Lastly, subtract 312 from the given year of Christ, and divide the remainder by 15; and what remains after this division is the indiction for the given year: If nothing remains, the indiction is 15.

29
Variation of the golden numbers.

Although the above deficiency in the lunar circle of an hour and an half every 19 years be but small, yet in
N^o 79.

time it becomes so sensible as to make a whole natural day in 310 years. So that, although this cycle be of use, when the golden numbers are rightly placed against the days of the months in the kalendar, as in the Common Prayer Books, for finding the days of the mean conjunctions or oppositions of the sun and moon, and consequently the time of Easter; it will only serve for 310 years, old style. For as the new and full moons anticipate a day in that time, the golden numbers ought to be placed one day earlier in the kalendar for the next 310 years to come. These numbers were rightly placed against the days of new moon in the kalendar, by the council of Nice, A. D. 325; but the anticipation, which has been neglected ever since, is now grown almost into 5 days: And therefore all the golden numbers ought now to be placed 5 days higher in the kalendar for the old style than they were at the time of the said council; or 6 days lower for the new style, because at present it differs 11 days from the old.

In the first of the following tables the golden numbers under the months stand against the days of new moon in the left-hand column, for the new style; adapted chiefly to the second year after leap-year, as being the nearest mean for all the four; and will serve till the year 1900. Therefore, to find the day of new moon in any month of a given year till that time, look for the golden number of that year under the desired month, and against it you have the day of new moon in the left hand column. Thus, suppose it were required to find the day of new moon in September 1789; the golden number for that year is 4, which I look for under December, and right against it in the left-hand column you will find 17, which is the day of new moon in that month. N. B. If all the golden numbers, except 17 and 6, were set one day lower in the table, it would serve from the beginning of the year 1900 till the end of the year 2199. The table at the end of this section shows the golden number for 4000 years after the birth of Christ, by looking for the even hundreds of any given year at the left-hand, and for the rest to make up that year at the head of the table; and where the columns meet, you have the golden number (which is the same both in old and new style) for the given year. Thus, suppose the golden number was wanted for the year 1789; look for 1700 at the left-hand of the table, and for 89 at the top of it; then guiding your eye downward from 89 to over-against 1700, you will find 4, which is the golden number for that year.

But because the lunar cycle of 19 years sometimes includes five leap-years, and at other times only four, this table will sometimes vary a day from the truth in leap-years after February. And it is impossible to have one more correct, unless we extend it to four times 19 or 76 years; in which there are 19 leap-years without a remainder. But even then to have it of perpetual use, it must be adapted to the old style; because, in every centurial year not divisible by 4, the regular course of leap-years is interrupted in the new; as will be the case in the year 1800.

2. The *cycle of Easter*, also called the *Dionysian period*, is a revolution of 532 years, found by multiplying the solar cycle 28 by the lunar cycle 19. If the new moons did not anticipate upon this cycle, Easter-day would always

30
To find the golden number.

31
Dionysian period, or cycle of Easter.

always be the Sunday next after the first full moon which follows the 21st of March. But, on account of the above anticipation, to which no proper regard was had before the late alteration of the style, the ecclesiastic Easter has several times been a week different from the true Easter within this last century: which inconvenience is now remedied by making the table, which used to find Easter for ever, in the Common Prayer Book, of no longer use than the lunar difference from the new style will admit of.

The earliest Easter possible is the 22d of March, the latest the 25th of April. Within these limits are 35 days, and the number belonging to each of them is called the *number of direction*; because thereby the time of Easter is found for any given year.

32
Dominical
letter.

The first seven letters of the alphabet are commonly placed in the annual almanacs, to show on what days of the week the days of the months fall throughout the year. And because one of those seven letters must necessarily stand against Sunday, it is printed in a capital form, and called the *dominical letter*; the other six being inserted in small characters, to denote the other six days of the week. Now, since a common Julian year contains 365 days, if this number be divided by 7 (the number of days in a week) there will remain one day. If there had been no remainder, it is plain the year would constantly begin on the same day of the week: but since one remains, it is plain, that the year must begin and end on the same day of the week; and therefore the next year will begin on the day following. Hence, when January begins on Sunday, A is the dominical or Sunday letter for that year: Then, because the next year begins on Monday, the Sunday will fall on the seventh day, to which is annexed the seventh letter G, which therefore will be the dominical letter for all that year: and as the third year will begin on Tuesday, the Sunday will fall on the sixth day; therefore F will be the Sunday letter for that year. Whence it is evident, that the Sunday letters will go annually in a retrograde order thus, G, F, E, D, C, B, A. And, in the course of seven years, if they were all common ones, the same days of the week and dominical letters would return to the same days of the months. But because there are 366 days in a leap-year, if this number be divided by 7, there will remain two days over and above the 52 weeks of which the year consists. And therefore, if the leap-year begins on Sunday, it will end on Monday; and the next year will begin on Tuesday, the first Sunday whereof must fall on the sixth of January, to which is annexed the letter F, and not G, as in common years. By this means, the leap-year

returning every fourth year, the order of the dominical letters is interrupted; and the series cannot return to its first state till after four times seven, or 28 years; and then the same days of the months return in order to the same days of the week as before.

³³
Julian pe-
riod.

From the multiplication of the solar cycle of 28 years into the lunar cycle of 19 years, and the Roman indiction of 15 years, arises the great Julian period, consisting of 7980 years, which had its beginning 764 years before Strauchius's supposed year of the creation (for no later could all the three cycles begin together), and it is not yet completed: And therefore it includes all other cycles, periods, and eras. There is but one year in the whole period that has the same numbers for the three cycles of which it is made up: And therefore, if historians had remarked in their writings the cycles of each year, there had been no dispute about the time of any action recorded by them.

³⁴
To find the
year of the
Julian pe-
riod.

The Dionysian or vulgar era of Christ's birth was about the end of the year of the Julian period 4713; and consequently the first year of his age, according to that account, was the 4714th year of the said period. Therefore, if to the current year of Christ we add 4713, the sum will be the year of the Julian period. So the year 1789 will be found to be the 6502d year of that period. Or, to find the year of the Julian period answering to any given year before the first year of Christ, subtract the number of that given year from 4714, and the remainder will be the year of the Julian period. Thus, the year 585 before the first year of Christ (which was the 584th before his birth) was the 4129th year of the said period. Lastly, to find the

cycles of the sun, moon, and indiction for any given year of this period, divide the given year by 28, 19, and 15; the three remainders will be the cycles sought, and the quotients the numbers of cycles run since the beginning of the period. So in the above 4714th year of the Julian period, the cycle of the sun was 10, the cycle of the moon 2, and the cycle of indiction 4; the solar cycle having run through 168 courses, the lunar 248, and the indiction 314.

The vulgar era of Christ's birth was never settled ³⁵Year of
till the year 527, when Dionysius Exiguus, a Roman Christ's
abbot, fixed it to the end of the 4713th year of the birth when
Julian period, which was four years too late; for our settled.
Saviour was born before the death of Herod, who
sought to kill him as soon as he heard of his birth.
And, according to the testimony of Josephus (*B. xvii.*
ch. 8.), there was an eclipse of the moon in the time
of Herod's last illness; which eclipse appears by our
astronomical tables to have been in the year of the Ju-
lian period 4710, March 13th, at 3 hours past mid-
night, at Jerusalem. Now, as our Saviour must have
been born some months before Herod's death, since in
the interval he was carried into Egypt, the latest time
in which we can fix the true æra of his birth is about
the end of the 4709th year of the Julian period.

As there are certain fixed points in the heavens from ³⁶Eras or E-
which astronomers begin their computations, so there pochs.
are

are certain points of time from which historians begin to reckon; and these points or roots of time are called *eras* or *epochs*. The most remarkable eras are, those of the Creation, the Greek Olympiads, the building of Rome, the era of Nabonassar, the death of Alexander, the birth of Christ, the Arabian Hegira, and the Persian Jesdegird: All which, together with several others of less note, have their beginnings fixed by chronologers to the years of the Julian period, to the age of the world at those times, and to the years before and after the year of Christ's birth.

with the foundation of the city of Rome; that of the Greeks at the establishment of the Olympic games; that of Nebuchadnezzar, with the advancement of the first king of Babylon to the throne; the Yezdegirdic years, with the last king of the Persians of that name; the hegira of the Turks with the flight of Mahomet from Mecca to Medina, &c. The year of the birth of Christ was the 4713th year of the Julian period, according to the common method of reckoning. Astronomical chronology teaches us to calculate the precise year of the Julian period in which each of these epochs happened.

37
Historic
chronology.

Having thus treated, as fully as our limits will admit, of the various divisions of time, we must now consider the second part of chronology, *viz.* that which more immediately relates to history, and which has already been observed to have the four following foundations: 1. Astronomical observations, particularly of eclipses. 2. The testimonies of credible authors. 3. Epochs in history universally allowed to be true. 4. Ancient medals, coins, monuments, and inscriptions. We shall consider these four principal parts in the order they here stand.

I.

38
Of eclipses
of the sun
and moon.

IT is with great reason that the eclipses of the sun and moon, and the aspects of the other planets, have been called public and celestial characters of the times, as their calculations afford chronologers infallible proofs of the precise epochs in which a great number of the most signal events in history have occurred. So that in chronological matters we cannot make any great progress, if we are ignorant of the use of astronomic tables, and the calculation of eclipses. The ancients regarded the latter as prognostics of the fall of empires, of the loss of battles, of the death of monarchs, &c. And it is to this superstition, to this wretched ignorance, that we happily owe the vast labour that historians have taken to record so great a number of them. The most able chronologers have collected them with still greater labour. Calvisius, for example, founds his chronology on 144 eclipses of the sun, and 127 of the moon, that he says he had calculated. The grand conjunction of the two superior planets, Saturn and Jupiter, which, according to Kepler, occurs once in 800 years in the same point of the zodiac, and which has happened only eight times since the creation (the last time in the month of December 1603), may also furnish chronology with incontestable proofs. The same may be said of the transit of Venus over the sun, which has been observed in our days, and all the other uncommon positions of the planets. But among these celestial and natural characters of times, there are also some that are named *civil* or *artificial*, and which, nevertheless, depend on astronomic calculation.

Such are the solar and lunar cycles; the Roman indiction; the feast of Easter; the bissextile year; the jubilees; the sabbatic years; the combats and Olympic games of the Greeks; and hegira of the Mahometans, &c. And to these may be added the periods, eras, epochs, and years of different nations, ancient and modern. We shall only remark on this occasion, that the period or era of the Jews commences with the creation of the world; that of the ancient Romans

II.

39
Of the tes-
timony of
authors.

THE testimony of authors is the second principal part of historic chronology. Though no man whatever has a right to pretend to infallibility, or to be regarded as a sacred oracle, it would, however, be making a very unjust judgment of mankind, to treat them all as dupes or impostors; and it would be an injury offered to public integrity, were we to doubt the veracity of authors universally esteemed, and of facts that are in themselves right worthy of belief. It would be even a kind of infatuation to doubt that there have been such cities as Athens, Sparta, Rome, Carthage, &c. or that Xerxes reigned in Persia, and Augustus in Rome: whether Hannibal ever was in Italy; or that the emperor Constantine built Constantinople, &c. The unanimous testimony of the most respectable historians will not admit any doubt of these matters. When an historian is allowed to be completely able to judge of an event, and to have no intent of deceiving by his relation, his testimony is irrefutable. But to avoid the danger of adopting error for truth, and to be satisfied of a fact that appears doubtful in history, we may make use of the four following rules, as they are founded in reason.

1. We ought to pay a particular regard to the testimonies of those who wrote at the same time the events happened, and that have not been contradicted by any cotemporary author of known authority. Who can doubt, for example, of the truth of the facts related by admiral Anson, in the history of his voyage round the world? The admiral saw all the facts there mentioned with his own eyes, and published his book when two hundred companions of his voyage were still living in London, and could have contradicted him immediately, if he had given any false or exaggerated relations.

2. After the cotemporary authors, we should give more credit to those who lived near the time the events happened, than those who lived at a distance.

3. Those doubtful histories, which are related by authors that are but little known, can have no weight if they are at variance with reason, or established tradition.

4. We must distrust the truth of a history that is related by modern authors, when they do not agree among themselves in several circumstances, nor with ancient historians, who are to be regarded as original sources. We should especially doubt the truth of those brilliant portraits, that are drawn at pleasure by such as never knew the persons they are intended for, and even made several centuries after their decease.

The most pure and most fruitful source of ancient history

history is doubtless to be found in the Holy Bible. Let us here for a moment cease to regard it as divine, and let us presume to consider it as a common history. Now, when we regard the writers of the books of the Old Testament, and consider them sometimes as authors, sometimes as ocular witnesses, and sometimes as respectable historians; whether we reflect on the simplicity of the narration, and the air of truth that is there constantly visible; or, when we consider the care that the people, the governments, and the learned men of all ages, have taken to preserve the true text of the Bible; or that we have regard to the happy conformity of the chronology of the holy scriptures with that of profane history: or, if we observe the admirable harmony that is between these books and the most respectable historians, as Josephus and others: and lastly, when we consider that the books of the holy scripture furnish us alone with an accurate history of the world from the creation, through the line of patriarchs, judges, kings, and princes of the Hebrews; and that we may, by its aid, form an almost entire series of events down to the birth of Christ, or the time of Augustus, which comprehends a space of about 4000 years, some small interruptions excepted, and which are easily supplied by profane history: when all these reflections are justly made, we must constantly allow that the scriptures form a book which merits the first rank among all the sources of ancient history. It has been objected, that this book contains contradictions; but the most able interpreters have reconciled these seeming contradictions. It has been said, that the chronology of the Hebrew text and the Vulgate do not agree with the chronology of the version of the Septuagint; but the soundest critics have shown that they may be made to agree. It has been observed, moreover, that the scriptures abound with miracles and prodigies; but they are miracles that have really happened: and what ancient history is there that is not filled with miracles, and other marvellous events? And do we for that reject their authority? Cannot the true God be supposed to have performed those miracles which Pagan historians have attributed to their false divinities? Must we pay no regard to the writings of Livy, because his history contains many fabulous relations?

III.

⁴⁰
Epochs.

THE *epochs* form the third principal part of chronology. These are those fixed points in history that have never been contested, and of which there can, in fact, be no doubt. Chronologers fix on the events that are to serve as epochs, in a manner quite arbitrary; but this is of little consequence, provided the dates of these epochs agree, and that there is no contradiction in the facts themselves. When we come to treat expressly on history, we shall mention, in our progress, all the principal epochs.

IV.

⁴¹
Medals, &c.

MEDALS, monuments, and inscriptions, form the fourth and last principal part of chronology. It is scarce more than 150 years since close application has been made to the study of these; and we owe to the celebrated Spanheim the greatest obligations, for the

progress that is made in this method: his excellent work, *De præstantia et usu numismatum antiquorum*, has shown the great advantages of it; and it is evident that these monuments are the most authentic witnesses that can be produced. It is by the aid of medals that M. Vaillant has composed his judicious history of the kings of Syria, from the time of Alexander the Great to that of Pompey: they have been, moreover, of the greatest service in elucidating all ancient history, especially that of the Romans; and even sometimes that of the middle age. Their use is more fully spoken of in the article MEDALS. What we here say of medals, is to be understood equally, in its full force, of ancient inscriptions, and of all other authentic monuments that have come down to us.

Every reader, endowed with a just discernment, will readily allow that these four parts of chronology afford clear lights, and are excellent guides to conduct us through the thick darkness of antiquity. That impartiality, however, which directs us to give a faithful relation of that which is true and false, of the certainty and uncertainty of all the sciences, obliges us here freely to confess, that these guides are not infallible, nor the proofs that they afford mathematical demonstrations. In fact, with regard to history in general, and ancient history in particular, something must be always left to conjecture and historic faith. It would be an offence against common probity, were we to suffer ourselves to pass over in silence those objections which authors of the greatest reputation have made against the certainty of chronology. We shall extract them from their own works; and we hope that there is no magistrate, theologian, or public professor in Europe, who would be mean enough to accuse us of a crime, for not unworthily disguising the truth.

1. The prodigious difference there is between the Septuagint Bible and the Vulgate, in point of chronology, occasions an embarrassment, which is the more difficult to avoid, as we cannot positively say on which side the error lies. The Greek Bible counts, for example, from the creation of the world to the birth of Abraham, 1500 years more than the Hebrew and Latin Bibles, &c. 2. How difficult is it to ascertain the years of the judges of the Jewish nation, in the Bible? What darkness is spread over the succession of the kings of Judah and Israel? The calculation of time is there so inaccurate, that the scripture never marks if they are current or complete years. For we cannot suppose that a patriarch, judge, or king, lived exactly 60, 90, 100, or 969 years, without any odd months or days. 3. The different names that the Assyrians, Egyptians, Persians, and Greeks, have given to the same prince, have contributed not a little to embarrass all ancient chronology. Three or four princes have borne the name of Assuerus, though they had also other names. If we did not know that Nabucodonosor, Nabucodrosor, and Nabucolassar, were the same name, or the name of the same man, we should scarcely believe it. Sargon is Sennacherib; Ozias is Azarias; Sedecias is Mathanias; Joachas is also called Sellum; Asaraddon, which is pronounced indifferently Efarhaddon and Asarhaddon, is called Asenaphar by the Cuthæans; and by an oddity of which we do not know the origin, Sardanapalus is called

by the Greeks Tenos Concoleros. 4. There remain to us but few monuments of the first monarchs of the world. Numberless books have been lost, and those which have come down to us are mutilated or altered by transcribers. The Greeks began to write very late. Herodotus, their first historian, was of a credulous disposition, and believed all the fables that were related by the Egyptian priests. The Greeks were in general vain, partial, and held no nation in esteem but their own. The Romans were still more infatuated with notions of their own merit and grandeur: their historians were altogether as unjust as was their senate, toward other nations that were frequently far more respectable. 5. The eras, the years, the periods and epochs, were not the same in each nation; and they, moreover, began at different seasons of the year. All this has thrown so much obscurity over chronology, that it appears to be beyond all human capacity totally to disperse it.

Christianity itself had subsisted near 1200 years, before they knew precisely how many years had passed since the birth of our Saviour. They saw clearly that the vulgar era was defective, but it was a long time before they could comprehend that it required four whole years to make up the true period. Abbe' Denis the Little, who in the year 532 was the first among the Christians to form the era of that grand epoch, and to count the years from that time, in order to make their chronology altogether Christian, erred in his calculation, and led all Europe into his error. They count 132 contrary opinions of different authors concerning the year in which the Messiah appeared on the earth. M. Vallemont names 64 of them, and all celebrated writers. Among all these authors, however, there is none that reckon more than 7000, nor less than 3700 years. But even this difference is enormous. The most moderate fix the birth of Christ in the 4000th year of the world. The reasons, however, on which they found their opinion, appear to be sufficiently arbitrary.

Be these matters, however, as they may, the wisdom of Providence has so disposed all things, that there remain sufficient lights to enable us nearly to connect the series of events: for in the first 3000 years of the world, where profane history is defective, we have the chronology of the Bible to direct us; and after that period, where we find more obscurity in the chronology of the holy scriptures, we have, on the other hand, greater lights from profane authors. It is at this period that begins the time which Varro calls *historic*: as, since the time of the Olympiads, the truth of such events as have happened shines clear in history. Chronology, therefore, draws its principal lights from history; and, in return, serves it as a guide. Referring the reader, therefore, to the article HISTORY, and the *Chart* thereto annexed, we shall conclude the present article with

ACHRONOLOGICAL TABLE of Remarkable Events, Discoveries, and Inventions, from the Creation to the Year 1783.

Before Christ.

4008 THE creation of the world, and Adam and Eve.
4007 The birth of Cain, the first who was born of a woman.

- 3017 Enoch, for his piety, is translated to heaven.
- 2352 The old world is destroyed by a deluge which continued 377 days.
- 2247 The tower of Babel is built about this time by Noah's posterity, upon which God miraculously confounds their language, and thus disperses them into different nations.
- 2207 About this time, Noah is, with great probability, supposed to have parted from his rebellious offspring, and to have led a colony of some of the more tractable into the east, and there either he or one of his successors to have founded the ancient Chinese monarchy.
- 2234 The celestial observations are begun at Babylon, the city which first gave birth to learning and the sciences.
- 2188 Misraim, the son of Ham, founds the kingdom of Egypt, which lasted 1663 years, down to the conquest of Cambyfes, in 525 before Christ.
- 2059 Ninus, the son of Belus, founds the kingdom of Assyria, which lasted above 1000 years, and out of its ruins were formed the Assyrians of Babylon, those of Nineveh, and the kingdom of the Medes.
- 1985 The covenant of God made with Abram, when he leaves Haran to go into Canaan, which begins the 430 years of sojourning.
- 1961 The cities of Sodom and Gomorra are destroyed for their wickedness by fire from heaven.
- 1856 The kingdom of Argos, in Greece, begins under Inachus.
- 1822 Memnon, the Egyptian, invents the letters.
- 1715 Prometheus first struck fire from flints.
- 1635 Joseph dies in Egypt.
- 1574 Aaron born in Egypt; 1490, appointed by God first high-priest of the Israelites.
- 1571 Moses, brother to Aaron, born in Egypt, and adopted by Pharaoh's daughter, who educates him in all the learning of the Egyptians.
- 1556 Cecrops brings a colony of Saïtes from Egypt into Attica, and begins the kingdom of Athens in Greece.
- 1555 Moses performs a number of miracles in Egypt, and departs from that kingdom, together with 600,000 Israelites, besides children, which completed the 430 years of sojourning. They miraculously pass through the Red Sea, and come to the desert of Sinai, where Moses receives from God, and delivers to the people, the Ten Commandments, and the other laws, and sets up the tabernacle, and in it the ark of the covenant.
- 1546 Scamander comes from Crete into Phrygia, and begins the kingdom of Troy.
- 1515 The Israelites, after sojourning in the Wilderness forty years, are led under Joshua into the land of Canaan, where they fix themselves, after having subdued the natives; and the period of the sabbatical year commences.
- 1503 The deluge of Deucalion.
- 1496 The council of Amphictyons established at Thermopylae.
- 1493 Cadmus carried the Phenician letters into Greece, and built the citadel of Thebes.
- 1490 Sparta built by Lacedemon.

Before
Christ.

- 1485 The first ship that appeared in Greece was brought from Egypt by Danaus, who arrived at Rhodes, and brought with him his fifty daughters.
- 1480 Troy built by Dardanus.
- 1452 The Pentateuch, or five first books of Moses, are written in the land of Moab, where he died the year following, aged 110.
- 1406 Iron is found in Greece, from the accidental burning of the woods.
- 1344 The kingdom of Mycenæ begins.
- 1326 The Isthmian games instituted at Corinth.
- 1325 The Egyptian canicular year began July 20th.
- 1307 The Olympic games instituted by Pelops.
- 1300 The Lupercalia instituted.
- 1294 The first colony came from Italy into Sicily.
- 1264 The second colony came from Italy into Sicily.
- 1252 The city of Tyre built.
- 1243 A colony of Arcadians conducted by Evander into Italy.
- 1233 Carthage founded by the Tyrians.
- 1225 The Argonautic expedition.
- 1204 The rape of Helen by Paris, which gave rise to the Trojan war, ending with the destruction of the city in 1184.
- 1176 Salamis in Cyprus built by Teucer.
- 1152 Ascanius builds Alba Longa.
- 1130 The kingdom of Sicyon ended.
- 1124 Thebes built by the Bœotians.
- 1115 The mariner's compass known in China.

- 1595 The same observed by Tycho-Brache to be $23^{\circ} 29' 25''$.
- 1596 A great earthquake at Japan.
- 1597 Watches first brought into England from Germany.
- 1598 The edict of Nantes by Henry IV. of France.
- 1602 Decimal arithmetic invented at Bruges.
- 1603 Queen Elizabeth (the last of the Tudors) dies, and nominates James VI. of Scotland as her successor; which unites both kingdoms under the name of Great Britain.
- 1605 The Gunpowder-plot discovered at Westminster; being a project to blow up the king and both houses of Parliament.
- 1606 Oaths of allegiance first administered in England.
- 1608 Colonies sent from England to Virginia.
- 1609 The independency of the United States acknowledged by Spain.
- 1610 Galileo, of Florence, first discovers the satellites about the planet Jupiter, by the telescope, lately invented in Germany.
- Henry IV. is murdered at Paris by Ravallac, a priest.
- Thermometers invented by Diebel, a Dutchman.
- 1611 Baronets first created in England by James I. May 22.
- An earthquake at Constantinople; 200,000 persons died there of the plague.
- 1612 The north-west passage to China attempted in vain by the English.
- 1614 Napier of Marcheston, in Scotland, invents the logarithms.
- Sir Hugh Middleton brings the new river to London from Ware.
- 1616 The first permanent settlement in Virginia.
- 1619 W. Harvey, an Englishman, confirms the doctrine of the circulation of the blood, which had been first broached by Servetius, a French physician, in 1553.
- 1620 The broad silk manufacture from raw silk, introduced into England.
- Barbadoes discovered by Sir William Courteen.
- Navarre united to France.
- Copper-money first introduced in England.
- 1621 New England planted by the Puritans.
- The two parties of Whigs and Tories formed in England.
- 1622 The Palatinate reduced by the Imperialists.
- 1623 The knights of Nova Scotia instituted.
- 1624 Massacre of the English at Amboyna.
- 1625 King James dies, and is succeeded by his son, Charles I.
- 1625 The island of Barbadoes, the first English settlement in the West Indies, is planted.
- 1631 The transit of Mercury over the sun's disk, first observed by Gassendi.
- A great eruption of Vesuvius.
- 1632 The battle of Lutzen, in which Gustavus Adolphus, king of Sweden, and head of the Protestants in Germany, is killed.
- 1633 Galileo condemned by the Inquisition at Rome.
- Louisiana discovered by the French.
- 1635 Province of Maryland planted by Lord Baltimore.
- Regular posts established from London to Scotland, Ireland, &c.
- 1636 A transit of Mercury over the sun's disk observed by Cassini.
- 1639 A transit of Venus over the sun's disk, first observed by Mr Horrox, November 24th. O. S. 3 h 15' P. M.
- 1640 King Charles disoblige his Scottish subjects; on which their army, under general Lesley, enters England, and takes Newcastle, being encouraged by the malecontents in England.
- The massacre in Ireland, when 40,000 English Protestants were killed.
- The independency of Portugal recovered by John duke of Braganza.
- 1642 King Charles impeaches five refractory members, which begins the civil wars in England.
- 1643 Excise on beer, ale, &c. first imposed by parliament.
- Barometers invented by Torricelli.
- 1648 A new star observed in the tail of the Whale by Fabricius.
- 1649 Charles I. beheaded by Cromwell at Whitehall, January 30, aged 49.
- Pendulums first applied to clocks by Huygens.
- 1651 The sect called *Quakers* appeared in England.
- 1652 The Dutch colony at the Cape of Good Hope established.
- 1654 Cromwell assumes the protectorship.
- The air-pump invented by Otto Guericke of Magdeburg.
- 1655 The English, under Admiral Penn, take Jamaica from the Spaniards.
- One of Saturn's satellites observed by Huygens.
- 1658 Cromwell dies, and is succeeded in the protectorship by his son Richard.
- 1660 King Charles II. is restored by Monk, commander of the army, after an exile of twelve years in France and Holland.
- The people of Denmark, being oppressed by the nobles, surrender their privileges to Frederic III. who becomes absolute.
- 1661 The obliquity of the ecliptic observed by Hevelius to be $23^{\circ} 29' 7''$.
- 1662 The Royal Society established at London by Charles II.
- 1663 Carolina planted: 1728, divided into two separate governments.
- Prussia declared independent of Poland.
- 1664 The New Netherlands in North America conquered from the Swedes and Dutch by the English.

After
Christ.

- 1665 The plague rages in London, and carries off 68,000 persons.
The magic lantern invented by Kircher.
- 1666 The great fire of London began Sept. 2. and continued three days, in which were destroyed 13,000 houses and 400 streets.
Tea first used in England.
- 1667 The peace of Breda, which confirms to the English the New Netherlands, now known by the names of Pennsylvania, New York, and New Jersey.
- 1668 — ditto, Aix la Chapelle.
St James's Park planted, and made a thoroughfare for public use by Charles II.
- 1669 The island of Candia taken by the Turks.
- 1670 The English Hudson's Bay company incorporated.
The obliquity of the ecliptic observed by Mengoli to be $23^{\circ} 28' 24''$.
- 1672 Louis XIV. over-runs great part of Holland, when the Dutch opened their sluices, being determined to drown their country and retire to their settlements in the East Indies.
African company established.
The obliquity of the ecliptic observed by Richer to be $23^{\circ} 28' 54''$.
- 1677 The micrometer invented by Kircher.
- 1678 The peace of Nimeguen.
The habeas corpus act passed.
A strange darkness at noon-day, Jan. 12.
- 1680 A great comet appeared, and from its nearness to our earth alarmed the inhabitants. It continued visible from Nov. 3. to March 9.
William Penn, a Quaker, receives a charter for planting Pennsylvania.
- 1683 India stock sold from 360 to 500 *per cent*.
- 1685 Charles II. dies, aged 55, and is succeeded by his brother James II.
The Duke of Monmouth, natural son to Charles II. raises a rebellion, but is defeated at the battle of Sedgmore and beheaded.
The edict of Nantes is revoked by Louis XIV. and the Protestants are greatly distressed.
- 1686 The Newtonian philosophy published.
- 1687 The palace of Versailles, near Paris, finished by Louis XIV.
- 1688 The Revolution in Great Britain begins Nov. 5. King James abdicates, and retires to France, December 3.
King William and Queen Mary, daughter and son-in-law to James, are proclaimed February 16.
Viscount Dundee stands out for James in Scotland, but is killed by General Mackay at the battle of Killycrankie; upon which the Highlanders, wearied with repeated misfortunes, disperse.
Smyrna destroyed by an earthquake.
- 1689 The land-tax passed in England.
The toleration-act passed in ditto.
Several bishops are deprived for not taking the oaths to William.
William Fuller, who pretended to prove the Prince of Wales spurious, was voted by the commons to be a notorious cheat, impostor, and false accuser.

After
Christ.

- 1689 Episcopacy abolished in Scotland.
- 1690 The battle of the Boyne, gained by William against James, in Ireland.
- 1691 The war in Ireland finished, by surrender of Limerick to William.
The obliquity of the ecliptic observed by Flamstead to be $23^{\circ} 28' 32''$.
- 1692 The English and Dutch fleets, commanded by Admiral Russel, defeat the French fleet off La Hogue.
The massacre of Glencoe in Scotland, Jan. 31. O. S.
Earthquakes in England and Jamaica, September 8.
Hanover made an electorate of the empire.
- 1693 Bayonets at the end of loaded muskets first used by the French against the confederates in the battle of Turin.
Bank of England established by King William.
The first public lottery was drawn this year.
- 1694 Queen Mary dies at the age of 33, and William reigns alone.
Stamp duties instituted in England.
- 1696 The peace of Ryfwick.
- 1699 The Scots settled a colony at the isthmus of Darien in America, and called it *Caledonia*.
- 1700 Charles XII. of Sweden begins his reign.
King James II. dies at St Germain in the 68th year of his age.
- 1701 Prussia erected into a kingdom.
Society for the propagation of the gospel in foreign parts established.
- 1702 King William dies, aged 50, and is succeeded by Queen Anne, daughter to James II. who, with the Emperor and States General, renews the war against France and Spain.
The French sent colonies to the Mississippi.
- 1703 The obliquity of the ecliptic observed by Bianchini to be $23^{\circ} 28' 25''$.
- 1704 Gibraltar taken from the Spaniards by Admiral Rooke.
The battle of Blenheim won by the Duke of Marlborough and allies against the French.
The court of Exchequer instituted in England.
- 1706 The treaty of Union betwixt England and Scotland, signed July 22.
The battle of Ramillies won by Marlborough and the allies.
- 1707 The first British parliament.
The allies defeated at Almanza.
- 1708 Minorca taken from the Spaniards by General Stanhope.
The battle of Oudenarde won by Marlborough and the allies.
- 1709 Peter the Great, czar of Moscovy, defeats Charles XII. at Poltowa, who flies to Turkey.
The battle of Malplaquet won by Marlborough and the allies.
- 1710 Queen Anne changes the Whig ministry for others more favourable to the interest of her brother the late Pretender.
The cathedral church of St Paul, London, rebuilt by Sir Christopher Wren in 37 years, at one million expence, by a duty on coals.
The English South-sea company began.

1712 Duke

After
Christ.

After
Christ.

- 1712 Duke of Hamilton and Lord Mohun killed in a duel in Hide-Park.
- 1713 The peace of Utrecht, whereby Newfoundland, Nova Scotia, New Britain, and Hudson's Bay, in North America, were yielded to Great Britain; Gibraltar and Minorca, in Europe, were also confirmed to the said crown by this treaty.
- 1714 Queen Anne dies, at the age of 50, and is succeeded by George I.
Interest reduced to five *per cent*.
- 1715 Louis XIV. dies, and is succeeded by his great-grandson Louis XV. the late king of France.
The rebellion in Scotland begins in September under the Earl of Mar, in favour of the Pretender. The action of Sheriffmuir, and the surrender of Preston, both in November, when the rebels disperse.
The obliquity of the ecliptic observed by Louville to be $23^{\circ} 28' 24''$.
- 1716 The Pretender married the princess Sobieska, grand-daughter of John Sobieski, late king of Poland.
An act passed for septennial parliaments.
- 1718 Sardinia erected into a kingdom, and given to the duke of Savoy.
- 1719 The Mississippi scheme at its height in France.
Lombe's silk-throwing machine, containing 26,586 wheels, erected at Derby: takes up one-eighth of a mile; one water-wheel moves the rest; and in 24 hours it works 318,504,960 yards of organzine silk thread.
- 1720 The South-sea scheme in England begun April 7. was at its height at the end of June, and quite sunk about September 29.
A great earthquake in China.
- 1724 An earthquake in Denmark.
- 1727 King George dies, in the 68th year of his age; and is succeeded by his only son, George II.
Inoculation first tried on criminals with success.
Russia, formerly a dukedom, is now established as an empire.
The aberration of the fixed stars discovered and accounted for by Dr Bradley.
- 1732 Kouli Khan usurps the Persian throne, conquers the Mogul empire, and returns with two hundred thirty-one millions Sterling.
Several public-spirited gentleman begin the settlement of Georgia in North America.
- 1733 The Jesuits expelled from Paraguay.
- 1736 Capt. Porteous having ordered his soldiers to fire upon the populace at an execution of a smuggler, is himself hanged by the mob at Edinburgh.
A transit of Mercury observed by Cassini.
- 1737 A dreadful hurricane at the mouth of the Ganges, Oct. 10.
- 1738 Westminster-bridge, consisting of 15 arches, begun; finished in 1750, at the expence of 389,000*l*. defrayed by parliament.
The order of St Januarius established at Naples.
- 1739 Letters of marque issued out in Britain against Spain July 21. and war declared, Oct. 23.
The empire of Indostan ruined by Kouli Khan.
An intense frost in Britain.
- 1743 The battle of Dettingen won by the English and allies in favour of the Queen of Hungary.

- 1743 A dreadful plague in Sicily.
- 1744 War declared against France.—Commodore Anson returns from his voyage round the world.
- 1745 The allies lose the battle at Fontenoy.
The rebellion breaks out in Scotland, and the Pretender's army defeated by the Duke of Cumberland at Culloden, April 16. 1746.
- 1746 British Linen Company erected.
Lima destroyed by an earthquake.
- 1747 Kouli Khan murdered.
- 1748 The peace of Aix-la-Chapelle, by which a restitution of all places taken during the war was to be made on all sides.
- 1749 The interest on the British funds reduced to 3 *per cent*.
British herring-fishery incorporated.
The colony of Nova Scotia founded.
- 1750 Earthquake in England.
- 1751 Frederic prince of Wales, father to his present majesty, died.
Antiquarian society at London incorporated.
- 1752 The new stile introduced into Great Britain; the 3d of September being counted the 14th.
- 1753 The British museum erected at Montague-house.
Society of arts, manufactures, and commerce, instituted in London.
- 1754 A dreadful eruption of mount *Ætna*.
A great earthquake at Constantinople, Cairo, &c. Sept. 2d.
- 1755 Quito in Peru destroyed by an earthquake, April 28th.
Lisbon destroyed by an earthquake, Nov. 1st.
- 1756 146 Englishmen are confined in the black hole at Calcutta in the East Indies by order of the nabob, and 123 found dead next morning.
Marine society established at London.
The King of Prussia commenced hostilities in the month of August in Saxony. Defeats the Austrians at Lo.
- 1757 Damien attempted to assassinate the French king.
The King of Prussia invades Bohemia. Defeats the Austrians at Reichenberg, April 21st, and at Prague, May 6th. Repulsed by Count Daun at Kolin, June 18th.
The allies defeated by the French at Hastenbeck, July 26th.
Convention of Closter Seven, Sep. 8th.
The King of Prussia defeats the French and Austrians at Rosbach, Nov. 5. The Prussians defeated near Breslaw, Nov. 22d. The Austrians defeated at Lissa, Dec. 5th.
- 1758 Senegal taken by the British, May 1st. They take Louisbourg, July 27th.
The King of Prussia defeats the Russians at Zorndorf, August 25th. Is defeated by Count Daun at Hoch-kirchen, Oct. 14th.
Goree taken by Commodore Keppel, Dec. 29th.
Attempt to assassinate the King of Portugal, Dec. 3.
- 1759 General Wolfe is killed in the battle of Quebec, which is gained by the British.
The French defeated by Prince Ferdinand at Bergen, April 13th.
Gaudaloupe taken by the British, May 1st.
King of Prussia defeated by the Russians at Cunnerrsdorf, Aug. 12th.

After
Christ.

- 1759 The French fleet defeated by Admiral Hawke, Nov. 20th.
Balbec and Tripoli destroyed by an earthquake, Dec. 5th.
- 1760 King George II. dies October 25th, in the 77th year of his age, and is succeeded by his present majesty, who, on the 22d of September 1761, married the princess Charlotte of Mecklenburgh Strelitz.
Blackfriars bridge, consisting of 9 arches, begun; finished 1770, at the expence of 152,840l. to be discharged by a toll.
A transit of Venus over the sun June 6th.
Earthquakes in Syria Oct. 13th.
The King of Prussia defeats the Austrians at Torgau Nov. 3d.
- 1761 Pondicherry taken by Col. Coote Jan. 15th.
Belleisle surrendered to the British Feb. 4th.
- 1762 War declared against Spain.
Peter III. emperor of Russia, is deposed, imprisoned, and murdered.
American philosophical society established in Philadelphia.
George Augustus Frederic, prince of Wales, born Aug. 12th.
Martinico surrendered to the British Feb. 4th.
Havannah surrendered to ditto Aug. 12th.
Manilla taken by ditto Oct. 6th.
- 1763 The definitive treaty of peace between Great Britain, France, Spain, and Portugal, concluded at Paris February 10th; which confirms to Great Britain the extensive provinces of Canada, East and West Florida, and part of Louisiana, in North America; also the islands of Granada, St Vincent, Dominica, and Tobago, in the West Indies.
The Jesuits expelled from France.
- 1764 The parliament granted 10,000l. to Mr Harrison for his discovery of the longitude by his time-piece.
Famine and pestilence in Italy.
An earthquake at Lisbon.
- 1765 His majesty's royal charter passed for incorporating the society of artists.
An act passed annexing the sovereignty of the island of Man to the crown of Great Britain.
- 1766 April 21st, a spot or macula of the sun, more than thrice the bigness of our earth, passed the sun's centre.
The American stamp-act repealed March 18th.
A great earthquake at Constantinople.
The Jesuits expelled from Bohemia and Denmark.
- 1767 The Jesuits expelled from Spain, Venice, and Genoa, April 2d.
Martinico almost destroyed by an earthquake.
The Protestants tolerated in Poland Nov. 2d.
- 1768 Academy of painting established in London.
The Turks imprison the Russian ambassador, and declare war against that empire.
The Jesuits expelled from Naples, Malta, and Parma.
- 1769 Paoli fled from Corsica June 13th. The island then reduced by the French.

After
Christ.

- 1770 An earthquake at St Domingo.
- 1771 Dr Solander and Mr Banks, in his majesty's ship the Endeavour, Lieut. Cook, return from a voyage round the world, having made several important discoveries in the Southseas.
An emigration of 500,000 Tourgouths from the coasts of the Caspian Sea to the frontiers of China.
- 1772 The King of Sweden changes the constitution from aristocracy to a limited monarchy.
The Pretender marries a princess of Germany, grand-daughter of Thomas late Earl of Aylebury.
The Emperor of Germany, Empress of Russia, and the King of Prussia, strip the King of Poland of a great part of his dominions, which they divide among themselves, in violation of the most solemn treaties.
- 1773 Captain Phipps is sent to explore the North Pole; but having made 81 degrees, is in danger of being locked up by the ice, and his attempt to discover a passage in that quarter proves fruitless.
The English East India company having, by conquest or treaty, acquired the extensive provinces of Bengal, Orixá, and Bahar, containing 15 millions of inhabitants, great irregularities are committed by their servants abroad; upon which government interferes, and sends out judges, &c. for the better administration of justice.
The war between the Russians and the Turks proves disgraceful to the latter, who lose the islands in the Archipelago, and by the sea are every where unsuccessful.
The society of Jesuits suppressed by the Pope's bull August 25th.
- 1774 Peace is proclaimed between the Russians and the Turks.
The British parliament having passed an act laying a duty of 3d. per pound upon all teas imported into America, the colonists, considering this as a grievance, deny the right of the British parliament to tax them.
The American colonies send deputies to Philadelphia, who assume the title of *The Congress of the Thirteen United Provinces*, and all the powers of government.
- 1775 The American war commences. Action at Bunker's Hill June 7th.
The Spaniards' land near Algiers and are defeated July 8th.
- 1776 The congress declare the United States of America independent of the crown and parliament of Great Britain.
The Americans receive a dreadful defeat at Long-Island August 27th.
- 1777 Philadelphia taken by the British Oct. 3d.
General Burgoyne with his army surrender to the Americans.
- 1779 A most extraordinary eruption of Vesuvius August 8th.
The siege of Gibraltar begun by the Spaniards July 8th.

- 1780 Jan. 14th, 6 h. A. M. the thermometer suspended in the open air at Glasgow, stood at 46° below 0.
The Spanish fleet defeated by Admiral Rodney Jan. 16th.
Charleston surrendered to the British May 12th.
A dreadful insurrection in London, and riots in many other places of the kingdom.
A great number of British ships taken by the combined fleets of France and Spain.
Lord Cornwallis defeats the Americans at Camden.
A dreadful hurricane in the Leeward Islands Oct. 9th.
An extraordinary storm of wind in England.
War declared against the Dutch Dec. 20th.
1781 A terrible engagement between the Dutch and British fleets near the Dogger Bank Aug. 5.
Lord Cornwallis with his army surrender to the united forces of France and America Oct. 18th.
1782 Minorca surrendered to the Spaniards February 4th.
The French fleet under De Grasse defeated

and almost destroyed by Admiral Rodney April 12th.

The Spanish floating batteries before Gibraltar entirely destroyed Sept. 12th.

1783 Preliminaries of a general peace signed. America declared independent Jan. 20th.

A dreadful earthquake, attended with many extraordinary circumstances, in Italy and Sicily.

The sun obscured by a kind of fog during the whole summer.

A volcanic eruption in Iceland surpassing any thing recorded in history. The lava spouted up in three places to the height of two miles perpendicular, and continued thus for two months; during which time it covered a tract of 3600 square miles of ground, in some places more than 100 feet deep.

A large meteor appears to the northward of Shetland, and takes its direction southward, with a velocity little inferior to that of the earth in its annual course round the sun. Its tract observed for more than 1000 miles.

Christ.

Chronome-
ter.

CHRONOMETER, in general, denotes any instrument or machine used in measuring time; such are dials, clocks, watches, &c. See DIAL, &c.

The term *chronometer*, however, is generally used in a more limited sense, for a kind of clock so contrived as to measure a small portion of time with great exactness, even to the sixteenth part of a second: of such a one there is a description in Desagulier's experimental philosophy, invented by the late ingenious Mr George Graham; which must be allowed to be of great use for measuring small portions of time in astronomical observations, the time of the fall of bodies, the velocity of running waters, &c. But long spaces of time cannot be measured by it with sufficient exactness, unless its pendulum be made to vibrate in a cycloid; because, otherwise it is liable to err considerably, as all clocks are which have short pendulums that swing in large arches of a circle.

There have been several machines contrived for measuring time, under the name of *chronometers*, upon principles very different from those on which clocks and watches are constructed.

Plate CXXXVI. fig. 1. represents an air-chronometer, which is constructed in the following manner. Provide a glass tube of about an inch in diameter, and three or four feet long: the diameter of the inside of this tube must be precisely equal in every part: at the bottom must be a small hole, closely covered with a valve. In the tube place a piston E, fig. 2. which is made to fit it exactly, and must be oiled, that it may move in the tube with the greatest freedom: in this piston there is a cock that shuts quite close; and from the top of it there goes a cord F, which passes through the handle G. The cock of the piston being closed, it is to be let down to the bottom of the tube, and being then drawn up to the top, the air will then rush in by the valve at the bottom of the tube, and support the piston. You are then to turn the cock, so as to make a very small vent; and the air passing slowly through

that vent, the piston will gradually descend, and show the hour, either by lines cut in the tube with a diamond, or marked with paint, or by small slips of paper painted on the glass. If this chronometer should go too fast or too slow, it may be easily regulated by altering the position of the cock in the piston, as it is on that the whole depends.

If, instead of marking the tube, you would have the time shown by a dial, it may be easily effected by placing an axis to which the hand of the dial is fixed, directly over the tube, and winding the string to which the piston is joined round that axis; for then, as the piston descends, the axis will gradually turn the hand, and show the hour: but it must be observed, that as the descent of the piston is not constantly regular, on account of the decrease of resistance from the quantity of the subjacent air as the piston descends, the axis therefore must not be a regular cylinder, but conical like the fusee of a watch, as in fig. 3. by which means the motion of the hand of the dial will be constant and regular.

Fig. 4. represents a lamp-chronometer. It consists of a chamber lamp A, which is a cylindrical vessel about three inches high, and one inch diameter, placed in the stand B. The inside of this vessel must be every where exactly of the same diameter. To the stand B is fixed the handle C, which supports the frame DEFG, about 12 inches high, and four wide. This frame is to be covered with oiled paper, and divided into twelve equal parts by horizontal lines; at the end of which are wrote the numbers for the hours, from 1 to 12, and between the horizontal lines are diagonals that are divided into halves, quarters, &c. On the handle B, and close to the glass, is fixed the style or gnomon H. Now, as the distance of the style from the flame of the lamp is only half an inch, if the distance of the frame from the style is only six inches, then, while the float that contains the light descends, by the decrease of the oil, one inch, the shadow

Chronome-
ter.

Chronome-
ter
||
Chrysa.

shadow of the style on the frame will ascend twelve inches, that is, its whole length, and show by its progression the regular increase of the hours, with their several divisions. It is absolutely necessary, however, that the oil used in this lamp be always of the same sort and quite pure, and that the wick also be constantly of the same size and substance, as it is on these circumstances, and the uniform figure of the vessel, that the regular progress of the shadow depends.

CHRONOMETER, among musicians, an instrument invented by *Loulie*, a French musician, for the purpose of measuring time by means of a pendulum. The form of the instrument, as described by him, is that of an Ionic pilaster, and is thus described by Malcolm in his *Treatise of Music*, p. 407.—“The chronometer consists of a large ruler or board, six feet or 72 inches long, to be set on end; it is divided into its inches, and the numbers set so as to count upwards; and at every division there is a small round hole, through whose centre the line of division runs. At the top of this ruler, about an inch above the division 72, and perpendicular to the ruler, is inserted a small piece of wood, in the upper side of which there is a groove, hollowed along from the end that stands out to that which is fixed in the ruler, and near each end of it a hole is made: through these holes a pendulum cord is drawn, which runs in the groove: at that end of the cord which comes through the hole furthest from the ruler, the ball is hung; and at the other end there is a small wooden pin, which can be put in any of the holes of the ruler: when the pin is in the uppermost hole at 72, then the pendulum from the top to the centre of the ball must be exactly 72 inches; and therefore, whatever hole of the ruler it is put in, the pendulum will be just so many inches as that figure at the hole denotes. The manner of using the machine is this: The composer lengthens or shortens his pendulum, till one vibration be equal to the designed length of his bar, and then the pin stands at a certain division, which marks the length of the pendulum; and this number being set with the cliff at the beginning of the song, is a direction for others how to use the chronometer in measuring the time according to the composer's design: for with the number is set the note, crotchet, or minim, whose value he would have the vibration to be; which in brisk duple time is best a minim or half bar, or even a whole bar, when that is but a minim; and in slow time a crotchet. In triple time, it would do well to be the third part or half, or fourth part of a bar; and in the simple triples that are allegro, let it be a whole bar. And if, in every time that is allegro, the vibration is applied to a whole or half bar, practice will teach us to subdivide it justly and equally. Observe, that, to make this machine of universal use, some canonical measure of the divisions must be agreed upon, that the figure may give a certain direction for the length of the pendulum.

CHROSTASIMA, in natural history, a genus of pellucid gems, comprehending all those which appear of one simple and permanent colour in all lights; such are the diamond, carbuncle, ruby, garnet, amethyst, sapphire, beryl, emerald, and the topaz. See DIAMOND, CARBUNCLE, &c.

CHRYSA, (anc. geog.), a town of Mysia, on the

sinus Adramyttenus; extinct in Pliny's time: it had a temple of Apollo Smintheus (Homer, Strabo). The country of the fair Chryseis, who gave first rise to the quarrel between Agamemnon and Achilles. Chrysalis.

CHRYsalis, or AURELIA, in natural history, a state of rest and seeming insensibility, which butterflies, moths, and several other kinds of insects, must pass through before they arrive at their winged or most perfect state.

In this state, no creatures afford so beautiful a variety as the butterfly kinds, and they all pass through this middle state without one exception. The figure of the aurelia or chrysalis generally approaches to that of a cone, or at least the hinder part of it is in this shape; and the creature, while in this state, seems to have neither legs nor wings, nor has any power of walking. It seems indeed to have hardly so much as life. It takes no nourishment in this state, nor has it any organs for taking any; and indeed its posterior part is all that seems animated, this having a power of giving itself some motions. The external covering of the chrysalis is cartilaginous, and considerably large, and is usually smooth and glossy: but some few of them have a few hairs; some are also as hairy as the caterpillars from which they are produced; and others are rough, and, as it were, shagreened all over.

In all of these there may be distinguished two sides; the one of which is the back, the other the belly of the animal. On the anterior part of the latter, there may always be distinguished certain little elevations running in ridges, and resembling the fillets wound about mummies: the part whence these have their origin, is esteemed the head of the animal. The other side, or back, is smooth, and of a rounded figure in most of the chrysalises; but some have ridges on the anterior part, and sides of this part; and these usually terminate in a point, and make an angular appearance on the chrysalis.

From this difference is drawn the first general distinction of these bodies. They are by this divided into two classes; the round and the angular kinds. The first are, by the French naturalists, called *seves*; from the common custom of calling the chrysalis of the silk-worm, which is round, by this name.

There is something more regular in this distinction than might at first be conceived; for the division is continued from the fly-state: the rounded chrysalises being almost all produced by the *phalæna* or moths; and the angular ones by the *papilio*, or day-flies. There are several subordinate distinctions of these kinds; but, in general, they are less different from one another than the caterpillars from whence they are produced.

The head of those of the first class usually terminates itself by two angular parts, which stand separate one from the other, and resemble a pair of horns. On the back, eminences and marks are discovered, which imagination may form into eyes, nose, chin, and other parts of the human face.

There is a great variety and a great deal of beauty in the figures and arrangement of the eminences and spots on the other part of the body of the chrysalises of different kinds. It is a general observation, that those chrysalises which are terminated by a single horn, afford day-butterflies of the kind of those which have
buttoned

Chrysalis.

buttoned antennæ, and whose wings, in a state of rest, cover the under part of their body, and which use all their six legs in walking, those of many other kinds using only four of them. Those chrysalises which are terminated by two angular bodies, and which are covered with a great number of spines, and have the figure of a human face on their back in the greatest perfection, afford butterflies of the day-kind; and of that class the characters of which are, their walking on four legs, and using the other two, that is, the anterior part, in the manner of arms or hands. The chrysalises which have two angular bodies on their heads, but shorter than those of the preceding, and whose back shows but a faint sketch of the human face, and which have fewer spines, and those less sharp, always turn to that sort of butterfly the upper wings of which are divided into segments, one of which is so long as to represent a tail, and whose under wings are folded over the upper part of the back. A careful observation will establish many more rules of this kind, which are not so perfect as to be free from all exceptions; yet are of great use, as they teach us in general what sort of fly we are to expect from the chrysalis, of which we know not the caterpillar, and therefore can only judge from appearances.

These are the principal differences of the angular chrysalises; the round ones also have their different marks not less regular than those.

The greater number of the round chrysalises have the hinder part of their body of the figure of a cone; but the upper end, which ought to be its circular plane base, is usually bent and rounded into a sort of knee: this is usually called the head of the chrysalis; but there are also some of this kind, the head of which is terminated by a nearly plane surface: some of the creeping ten-legged caterpillars give chrysalises of this kind, which have each of them two eminences that seem to bring them towards the angular kind.

Among the angular chrysalises there are some whose colours seem as worthy our observation as the shapes of the others. Many of them appear superbly clothed in gold. These elegant species have obtained the name of *chrysalis* and *aurelia*, which are derived from Greek and Latin words, signifying gold; and from these all other bodies of the same kind have been called by the same names, though less, or not at all, intitled to them. As some kinds are thus gilded all over, so others are ornamented with this gay appearance in a more sparing manner, having only a few spots of it in different places on their back and belly. These obvious marks, however, are not to be depended upon as certain characters of distinction: for accidents in the formation of the chrysalis may alter them; and those which naturally would have been gilded all over, may be sometimes only so in part; and either these or the others may, by accident, be so formed, as to show nothing of this kind at all, but be only of a dusky brown. Those, however, which have neither silver nor gold to recommend them to your eyes, do not want other colours, and those beautifully variegated. Some of them are all over of an elegant green, as is the chrysalis of the fennel-caterpillar; others of an elegant yellow; and some of a bright greenish tinge, variegated with spots of a shining black: we have a very beautiful instance of this last

kind in the chrysalis of the elegant cabbage-caterpillar. The general colour of the chrysalis of the common butterflies, however, is brown.

Some are also of a fine deep black; and of these many are so smooth and glossy, that they are equal to the finest Indian japan. The common caterpillar of the fig-tree gives an instance of one of these most beautiful glossy ones; the caterpillar of the vine affords another of these fine black chrysalises.

The rounded chrysalises do not afford any thing of that variety of colouring so remarkably beautiful in the angular ones; they are usually of a dusky yellow, in different shades, and are often variously spotted with black: but these, as well as all other chrysalises, before they arrive at their fixed colour, pass through several other temporary ones; some being of a different colour when first produced from the caterpillar, from what they are a few days afterwards; and some varying so greatly, though only in degree, as not to be distinguishable, even by the most conversant eye, from what they were when first produced. The green rough caterpillar of the cabbage has a chrysalis which is green at first; and from that gradually goes through all the shades of green to a faint yellow, which is its lasting colour; and one of the oak caterpillars yields a chrysalis beautifully spotted with red at its first appearance; but these spots change to brown for their fixed colour: the third day from their formation usually fixes their lasting colours; and if they are observed to turn black in any part after this time, it is a sign that they are dead or dying.

The several species of insects, as a fly, spider, and an ant, do not differ more evidently from one another in regard to appearance, than do a caterpillar, its chrysalis, and a butterfly produced from it; yet it is certain, that these are all the product of the same individual egg; and nothing is more certain, than that the creature which was for a while a caterpillar, is, after a certain time, a chrysalis, and then a butterfly. These great changes produced in so sudden a manner, seem like the *metamorphoses* recorded in the fables of the ancients; and indeed it is not improbable that those fables first took their origin from such changes.

The parts being distinguishable in the chrysalis, we easily find the difference of the species of the fly that is to proceed from it. The naked eye shows whether it be one of those that have, or of those that have not, a trunk; and the assistance of a microscope shows the antennæ so distinctly, that we are able to discern whether it belongs to the day or night class; and often to what genus, if not the very species: nay, in the plumose horned kinds, we may see, by the antennæ, whether a male or female phalæna is to be produced from the chrysalis; the horns of the female being in this state evidently narrower, and appearing less elevated above the common surface of the body, than those of the male.

All these parts of the chrysalis, however, though seen very distinctly, are laid close to one another, and seem to form only one mass; each of them is covered with its own peculiar membrane in this state, and all are surrounded together by a common one; and it is only through these that we see them; or rather we see on these the figures of all the parts moulded within,

Chrysalis.

and

Chrysalis. and therefore it requires attention to distinguish them. The chrysalis is soft when first produced, and is wetted on the front with a viscous liquor; its skin, though very tender at first, dries and hardens by degrees: but this viscous liquor, which surrounds the wings, legs, &c. hardens almost immediately; and in consequence fastens all those limbs, &c. into a mass, which were before loose from one another: this liquor, as it hardens, loses its transparence, and becomes brown; so that it is only while it is yet moist that these parts are to be seen distinct.

It is evident from the whole, that the chrysalis is no other than a butterfly, the parts of which are hid under certain membranes which fasten them together; and, when the limbs are arrived at their due strength, they become able to break through these membranes, and then expand and arrange themselves in their proper order.

The first metamorphosis, therefore, differs nothing from the second, except that the butterfly comes from the body of the caterpillar in a weak state, with limbs unable to perform their offices, whereas it comes from the chrysalis perfect.

*History of
Insects,
vol. i.
p. 2.—23.*

M. Reaumur has given us many curious observations on the structure and uses of the several coverings that attend the varieties of the caterpillar-kind in this state.

The creatures in general remain wholly immovable in this state, and seem to have no business in it but a patient attendance on the time when they are to become butterflies; and this is a change that can happen to them, only as their parts, before extremely soft and weak, are capable of hardening and becoming firm by degrees, by the transpiration of that abundant humidity which before kept them soft: and this is proved by an experiment of M. Reaumur, who, inclosing some chrysalises in a glass tube, found, after some time, a small quantity of water at the bottom of it; which could have come there no other way, but from the body of the inclosed animal. This transpiration depends greatly on the temperature of the air; it is increased by heat, and diminished by cold; but it has also its peculiarities in regard to the several species of butterfly to which the chrysalis belongs.

According to these observations, the time of the duration of the animal in the chrysalis state must be, in different species, very different; and there is indeed this wide difference in the extremes, that some species remain only eight days in this state, and others eight months.

We know that the caterpillar changes its skin four or five times during its living in that state; and that all these skins are at first produced with it from the egg, lying closely over one another. It parts with, or throws off all these one by one, as the butterfly, which is the real animal, all this time within, grows more and more perfect in the several first changes. When it throws off one, it appears in another skin exactly of the same form; but at its final change from this appearance, that is, when it throws off the last skin, as the creature within is now arrived at such a degree of perfection as to need no farther taking of nourishment, there is no farther need of teeth, or any of the other parts of a caterpillar. The creature, in this last change, proceeds in the very same manner as

Nº 80.

Chrysalis. in all the former, the skin opening at the back, and the animal making its way out in this shape. If a caterpillar, when about to throw off this last skin, be thrown into spirits of wine, and left there for a few days, the membranes within will harden, and the creature may be afterwards carefully opened, and the chrysalis taken out, in which the form of the tender butterfly may be traced in all its lineaments, and its eyes, legs, &c. evidently seen. It is not necessary, however, to seize upon this exact time for proving the existence of the chrysalis or butterfly in the caterpillar: for if one of these animals be thrown into spirit of wine, or into vinegar, some days before that time, and left there for the flesh to harden, it may afterwards be dissected, and all the lineaments of the butterfly traced out in it; the wings, legs, antennæ, &c. being as evident here, and as large, as in the chrysalis.

It is very plain from this, that the change of the caterpillar into chrysalis is not the work of a moment; but is carrying on for a long time before, even from the very hatching of the creature from the egg. The parts of the butterfly, however, are not disposed exactly in the same manner while in the body of the caterpillar, as when left naked in the form of the chrysalis: for the wings are proportionally longer and narrower, being wound up into the form of a cord; and the antennæ are rolled up on the head; the trunk is also twisted up and laid upon the head; but this in a very different manner from what it is in the perfect animal, and very different from that in which it lies within the chrysalis; so that the first formation of the butterfly in the caterpillar, by time arrives at a proper change of the disposition of its parts, in order to its being a chrysalis. The very eggs, hereafter to be deposited by the butterfly, are also to be found not only in the chrysalis, but in the caterpillar itself, arranged in their natural, regular order. They are indeed in this state very small and transparent; but after the change into the chrysalis, they have their proper colour.

As soon as the several parts of the butterfly, therefore, are arrived at a state proper for being exposed to the more open air, they are thrown out from the body of the caterpillar surrounded only with their membranes; and as soon as they are arrived after this at a proper degree of strength and solidity, they labour to break through these thinner coverings, and to appear in their proper and natural form. The time of their duration in this state of chrysalis is very uncertain, some remaining in it only a few days, others several months, and some almost a year in appearance. But there is a fallacy in this that many are not aware of. It is natural to think, that as soon as the creature has inclosed itself in its shell, be that of what matter it will, it undergoes its change into the chrysalis state. And this is the case with the generality: yet there are some which are eight or nine months in the shell before they become chrysalises; so that their duration in the real chrysalis state is much shorter than it naturally appears to be. M. Reaumur carefully watched the auriculated caterpillar of the oak in its several changes, and particularly from its chrysalis, which is of this last kind, into the fly; and has given an account of the method of this as an in-

Chrysalis. stance of the general course of nature in these operations.

The membranes which envelope the creature in this chrysalis state are at first tough and firm, and immediately touch the several parts of the inclosed animal; but by degrees, as these parts harden, they become covered, some with hairs, and others with scales. These, as they continue to grow, by degrees fall off the several particular membranes which cover the parts on which they are placed, to a greater distance, and by degrees loosen them from the limbs. This is one reason of those membranes drying and becoming brittle.

The middle of the upper part of the *CORSELET* is usually marked with a line which runs in a longitudinal direction; and this part is always more elevated than the rest, even in the conic kinds, which are no otherwise angular. This line is in some very bold and plain; in others, it is so faint as not to be distinguishable without glasses; but it is always in the midst of that line that the shell begins to open. The motion of the head of the butterfly backwards first occasions this crack; and a few repetitions of the same motion open it the whole length of the line.

The clearing itself, however, entirely, is a work of more time in this case, than is the passing of the chrysalis out of the body of the caterpillar. In that case there is a crack sufficiently large in the skin of the back, and the whole chrysalis being loose comes out at once. But in this case, every particular limb, and part of the body, has its separate case; and these are almost inconceivably thin and tender, yet it is necessary that every part be drawn out of them before it appear naked to the open air. As soon as all this is effected, and the animal is at full liberty, it either continues some time upon the remains of its covering, or creeps a little way distant from it, and there rests. The wings are what we principally admire in this creature. These are at this time so extremely folded up, and placed in so narrow a compass, that the creature seems to have none at all: but they by degrees expand and unfold themselves; and finally, in a quarter of an hour, or half an hour at the utmost, they appear at their full size, and in all their beauty. The manner of this sudden unfolding of the wings is this: the small figure they make when the creature first comes out of its membranes, does not prevent the observing that they are at that time considerably thick. This is owing to its being a large wing folded up in the nicest manner, and with folds so arranged as to be by no means sensible to the eye, for the wing is never seen to unfold; but, when observed in the most accurate manner, seems to grow under the eye to this extent. When the creature is first produced from the shell, it is every where moist and tender; even its wings have no strength or stiffness till they expand themselves; but they then dry by degrees, and, with the other parts, become rigid and firm. But if any accident prevents the wings from expanding at their proper time, that is, as soon as the creature is out of its shell, they never afterwards are able to extend themselves; but the creature continues to wear them in their contracted and wholly useless state; and very often, when the wings are in part extended before such an accident happens, it stops them in a partial extension, and the

VOL. IV. Part II.

creature must be contented to pass its whole life with them in that manner.

M. Reaumur has proved, that heat and cold make great differences in the time of hatching the butterfly from its chrysalis state: and this he particularly tried with great accuracy and attention, by putting them in vessels in warm rooms, and in ice-houses; and it seemed wholly owing to the hastening or retarding the evaporation of the abundant humidity of the animal in the chrysalis state, that it sooner or later appeared in the butterfly form. He varnished over some chrysalises, in order to try what would be the effect of thus wholly preventing their transpiration; and the consequence was, that the butterfly came forth from these two months later than their natural time. Thus was the duration of the animal in this state lengthened; that is, its existence was lengthened: but without any advantage to the creature, since it was in the time of its state of inaction, and probably of insensibility.

Though this was of no consequence, Mr Reaumur deduces a hint from it that seems to be of some use. He observes, that hens eggs, of which we make so many uses, and eat in so many forms, are properly a sort of chrysalis of the animal; their germ, after they are impregnated by the cock, containing the young animal alive, and waiting only a due degree of warmth to be hatched, and appear in its proper form. Eggs transpire notwithstanding the hardness of their shells; and when they have been long kept, there is a road found near one of their ends, between the shell and the internal membrane; this is a mark of their being stale, and is the effect of an evaporation of part of their humidity: and the same varnish which had been used to the chrysalis, being tried on eggs, was found to preserve them for two years, as fresh as if laid but the same day, and such as the nicest palate could not distinguish from those that were so. See EGGS.

It is not yet known how much farther this useful speculation might be carried, and whether it might not be of great use even to human life, to invent something that should act in the manner of this varnish, by being rubbed over the body, as the *athleta* did of old, and the savages of the West Indies do at this time, without knowing why. But to return to the insects which are the subjects of this article; their third state, that in which they are winged, is always very short, and seems destined for no other action but the propagation of the species. See PAPILIO.

CHRYSANTHEMUM, CORN-MARIGOLD: A genus of the polygamia superflua order, belonging to the syngenesia class of plants; and in the natural method ranking under the 49th order, *Compositae*. The receptacle is naked; the pappus marginated, or consisting only of a border; the calyx hemispherical and imbricated, with the marginal scales membranaceous. There are 19 species, of which the following are the most remarkable: 1. The serotinum is a native of North America. The roots of this plant creep far under the surface, and send up strong stalks more than four feet high, garnished with long sawed leaves ending in points. These stalks divide upward into many smaller; each being terminated by a large, white, radiated flower, which appears in the end of August or September. 2. The coronarium hath been long cultivated in the gardens on account of the beauty of its flowers.

Chrysan-
themum
||
Chrysippus.

flowers. It grows to the height of three feet, with a single upright stalk divided into numerous branches, garnished with pinnated leaves, and crowned with elegant compound flowers of different colours and properties. The varieties are, single and double flowers of a cream colour; yellow; yellow and white; brimstone-coloured; fistular, or quilled; or those with finely jagged leaves, and flowers of all the above colours and properties. All the varieties begin flowering in July: the flowers are exceedingly numerous, and exhibit a constant succession of full bloom till November; and both single and double are succeeded by abundance of seed. 3. The *putescens* is a native of the Canary islands. It rises with a shrubby stalk near two feet high, dividing into many branches, which are garnished with pretty thick succulent leaves, of a greyish colour, cut into many segments. The flowers come out from the wings of the leaves, growing upon naked footstalks singly, which greatly resemble those of chamomile. There is a succession of flowers on the same plant for the greatest part of the year, for which it is chiefly esteemed. This plant will perfect seeds in Britain when the seasons are favourable.

Culture. The first kind multiplies very fast by its creeping roots, and will thrive in any soil or situation. The second may be raised in abundance from seed, either in a hot-bed or warm border, in the spring, for transplanting; also by cuttings and slips of their branches in autumn. The latter method is practised only for the propagation of the fine doubles, for an early bloom the following summer; and the best time to perform it is in September, or early in October. Cut off at that time a quantity of the robust side shoots, from three to six inches long, without flowers; divest them of the lower leaves, and plant many of them together in large pots, within an inch or two of their tops, and two or three inches apart, give some water, and place them in the shade during the hot weather: by the end of October they will be rooted, when the pots are to be removed either into a greenhouse or garden-frame, for the winter; but the latter is the most eligible, where they may enjoy the full air in mild weather, and have occasional shelter from frost. In April they may be transplanted singly into borders, and some in pots. The plants thus raised will flower a month or six weeks sooner the succeeding summer than those raised in the spring from seed; but as they soon become barren, it is proper to have always a quantity of plants raised from the seed. The third sort may be raised either from seeds or cuttings, but requires to be sheltered in the greenhouse in winter.

CHRYSES, the priests of Apollo, father of Asty-nome, called from him *Chryseis*. When Lyrnessus was taken and the spoils divided among the conquerors, Chryseis fell to the share of Agamemnon. Chryses upon this went to the Grecian camp to solicit his daughter's restoration; and when his prayers were fruitless, he implored the aid of Apollo, who visited the Greeks with a plague, and obliged them to restore Chryseis.

CHRYSIIPPUS, a Stoic philosopher, born at Solos in Cilicia, was disciple to Cleanthus, Zeno's successor. He wrote many books, several of which related to logic. None of the philosophers spoke in

stronger terms of the fatal necessity of every thing, nor more pompously of the liberty of man, than the Stoics, Chrysippus in particular. He was so considerable among them, as to establish it into a proverb, that if it had not been for Chrysippus, the porch had never been. Yet the Stoics complained, as Cicero relates, that he had collected so many arguments in favour of the sceptical hypothesis, that he could not answer them himself; and thus had furnished Carneades, their antagonist, with weapons against them. There is an apophthegm of this philosopher preserved, which does him honour. Being told that some persons spoke ill of him, "It is no matter (said he), I will live so that they shall not be believed."

CHRYISIS, or GOLDEN-FLY, in natural history: A genus of insects belonging to the order of hymenoptera. The mouth is armed with jaws, but has no proboscis; the antennæ are filiform, bent, and consist of 12 articulations; the abdomen is arched, with a scale on each side; the anus is dentated, and armed with a sting; the wings lie plain; and the body appears as if gilt. There are several species; but the *ignita*, or flaming chrysis, is beautified with the most resplendent colours. The fore-part of its head is green and gold, and the hinder of a lovely azure. The thorax is likewise azured over, with a mixture of green, and terminates at its extremity with sharp points on both sides. The abdomen is green and gold before, and of a coppery-red behind, imitating molten copper highly polished. The whole insect is dotted on its upper part, which gives it a great resplendency of colour. The antennæ are black, and legs green intermixed with gold. This species dwells in holes of walls between the stones, and in the mortar that cements them. It is often seen issuing from such holes, where it nestles and performs its work. The larvæ, which resemble those of the wasp, likewise inhabit the holes of decayed walls.

CHRYSITRIX, in botany: A genus of the dioecia order, belonging to the polygamia class of plants. In the hermaphrodite the glume is two-valved, the corollæ from chaff numerous and bristly; many stamina, one within each chaff; one pistillum. The male is the hermaphrodite; there is no pistillum.

CHRYSOBALANUS, COCOA PLUM: A genus of the monogynia order, belonging to the icofandria class of plants; and in the natural method ranking under the 36th order, *Pomaceæ*. The calyx is quinquefid, the petals five; plum-kernel five-furrowed and five-valved. There is only one species, the *icaco*, which is a native of the Bahama islands and many other parts of America, but commonly grows near the sea. It rises with a shrubby stalk eight or nine feet high, sending out several side-branches, which are covered with a dark brown bark. The flowers are white, and are succeeded by plums like damsons; some blue, some red, and others yellow. The stone is shaped like a pear, and has five longitudinal furrows. The plums have a sweet luscious taste, and are brought to the tables of the inhabitants, by whom they are much esteemed.

CHRYSOCOMA, GOLDBY-LOCKS: A genus of the polygamia æqualis order, belonging to the syngenesia class of plants; and in the natural method ranking under the 49th order, *Compositæ*. The receptacle is

Chrysis
||
Chryso-
coma.

Chrysogonum
||
Chrysomela.

naked; the pappus simple; the calyx hemispherical and imbricated; the style hardly longer than the florets. There are nine species, the most remarkable of which are, the linosyris, the coma aurea, and the cornua. These are herbaceous flowering perennials, growing from one to two feet high, ornamented with narrow leaves, and compound floscular flowers of a yellow colour. They are easily propagated by dividing the roots or by cuttings; but the two last require to be sheltered in the green-house in winter.

CHRYSOGONUM, in botany: A genus of the polygamia necessaria order, belonging to the syngenesia class of plants; and in the natural method ranking under the 49th order, *Compositæ*. The receptacle is paleaceous; the pappus monophyllous, and tridentated; the calyx pentaphyllous; the seeds wrapped up each in a tetraphyllous calyculus, or little cup.

CHRYSOLARUS (Emanuel), one of those learned men in the 14th century who brought the Greek literature into the west. He was a man of rank; and descended from an ancient family, said to have removed with Constantine from Rome to Byzantium. He was sent into Europe by the emperor of the east to implore the assistance of the Christian princes. He afterwards taught at Florence, Venice, Pavia, and Rome; and died at Constantinople, in 1415, aged 47. He wrote a Greek grammar, and some other small pieces.

CHRYSOLITE, or YELLOWISH-GREEN TOPAZ; a precious stone of a grass green colour, found in the East Indies, Brazil, Bohemia, Saxony, Spain, in Auvergne and Bourbon in France, and in Derbyshire in England. Some are likewise found with volcanic lavas, as in the Vevarais, where some large lumps have been seen of 20 or 30 pounds weight; but it is remarkable, that some of these chrysolites are partly decomposed into an argillaceous substance. All chrysolites, however, are far from being of the same kind. The oriental is the same with the peridot, and differs only by its green hue from the sapphires, topazes, and rubies of the same denomination. This becomes electric by being rubbed; has a prismatic form of six, or sometimes of five striated faces; and does not lose its colour or transparency in the fire, which the common chrysolite often does; becoming either opaque, or melting entirely in a strong heat. The instant it melts, it emits a phosphoric light like the basis of alum and gypseous spar: with borax it produces a thin colourless glass. Its specific gravity is between 3.600 and 3.700; according to Brisson it is 2.7821, or 2.6923; and that of the Spanish chrysolite 3.0989.

The substance of this precious stone is lamellated in the direction of the axis of its primitive form: but the chrysolite from Saxony is foliated in a perpendicular direction to the same axis. The chrysolite of the ancients was the same gem which is now called *topaz*, and the name of itself indicates that it ought to be so. Pliny says that the colour of the chrysolite is yellow like gold.

CHRYSOLITE-Paste, a kind of glass made in imitation of natural chrysolite, by mixing two ounces of prepared crystal with ten ounces of red-lead, adding 12 grains of crocus martis made with vinegar; and then baking the whole for 24 hours, or longer, in a well luted cucurbit.

CHRYSOMELA, in zoology, a genus of insects

belonging to the order of coleoptera. The antennæ are shaped like bracelets, and thicker on the outside; and neither the breast nor the elytra are margined. There are no less than 122 species enumerated by Linnaeus, principally distinguished by differences in their colour. They are to be found almost every where, in woods, gardens, &c. Their progressive motion is slow; and some when caught emit an oily liquor of a disagreeable smell. The glittering colours with which several species of chrysomelæ are adorned, and which seem to exhibit the brilliancy of gold and copper, have occasioned their bearing that pompous name. The larvæ of these insects have in general an oval body, rather oblong and soft; on the fore-part of which are situated six feet, which are scaly, as is also the head. They prey upon the substance of leaves, rejecting the fibrous part. Those of the leaping chrysomelæ infest the cotyledons and tender leaves of plants. Of this genus is that very pernicious insect called by the country people the *turnip fly*, which infests turnips and many crops in the garden, destroying often whole fields while in their seedling leaves. In very hot summers they abound to an amazing degree, and, as you walk in a field or in a garden, make a pattering like rain, by jumping on the leaves of the turnips or cabbages. See Plate CXLIX.

CHRYSOPHYLLUM, or BULLY-TREE: A genus of the monogynia order, belonging to the pentandria class of plants; and in the natural method ranking under the 43d order, viz. *Dumosa*. The corolla is campanulated, decemfid, with the segments alternately a little patent. The fruit is a ten-seeded berry. There are two species, the cainito and glabrum, both natives of the West Indies. The first rises 30 or 40 feet high, with a large trunk covered with a brown bark, and divides into many flexible slender branches, which generally hang downward, garnished with spear-shaped leaves, whose under sides are of a bright russet colour. The flowers come out at the extremities of the branches, disposed in oblong bunches, which are succeeded by fruit of the size of a golden pippin, that are very rough to the palate, and astringent; but when kept some time mellow, as is practised here with medlars, they have an agreeable flavour. The second sort never rises to the height of the first, nor do the trunks grow to half the size; but the branches are slender and garnished with leaves like those of the first. The flowers come out in clusters from the side of the branches, which are succeeded by oval smooth fruit about the size of a bergamot pear. This contains a white clammy juice when fresh; but after being kept a few days, it becomes sweet, soft, and delicious. Inclosed are four or five black seeds about the size of those of a pomkin. Both these plants are frequently preserved in gardens where there are large stoves, and are propagated by seeds, but the plants can never bear the open air in this country.

CHRYSOPLENIUM, in botany: A genus of the digynia order, belonging to the decandria class of plants; and in the natural method ranking under the 12th order, *Succulentæ*. The calyx is quadrifid or quinquefid, and coloured; no corolla; the capsule bi-rostrated, unilocular and polyspermous.

CHRYSOPRASUS, or **CHRYSOPRASUS**, the 10th of the precious stones mentioned in the Revelations, as

Chrysophyllum
||
Chrysoprasus.

Chrysoprasus,
Chrysolite.

forming the foundation of the heavenly Jerusalem. The chrysoprasus is by mineralogists reckoned to be a variety of the chrysolite, and by Cronstedt called the *yellowish green and cloudy topaz*. He conjectures that it may perhaps be the substance which serves as a matrix to the chrysolite; as those that he had seen were like the clear veined quartz, called in Sweden *milk crystal*, which is the first degree of crystallization.

The chrysoprasus, according to M. Magellan, is of a green colour, deeper than the chrysolite, but with a yellowish tinge inclining to blue like the green leek. M. Achard says that it is never found crystallized, and that it is semitransparent. By others it is reckoned among the quartz, and its colour is supposed to be owing to the mixture of cobalt, as it gives a fine blue glass when melted with borax, or with fixed alkali. Mr Achard, however, found the glass of a deep yellow when the fusion was made with borax; and that it really contains some calx of copper instead of cobalt. Mr Dutens says, that some gold has been found in this kind of stone: but this last belongs in all probability, says M. Magellan, to another class of substances, viz. the vitreous spars.

To the latter belongs most probably the aventurine, whose colour is generally a yellow-brown red; though sometimes it inclines more to the yellow, or greenish, than to the red. These stones are not quite transparent: some indeed shine with such a brilliancy, as to render them of considerable value, but they are very rare. The common aventurine is but an artificial glass of various colours, with which powder of gold has been mixed; and these imitated aventurines so frequently excel the native ones in splendor, that the esteem of the latter is now much lowered. With regard to the chrysoprasus, its name from *πρασον*, shows it to be of a greenish-blue colour, like the leaves of a leek; it only differs from the chrysolite in its bluish hue.

CHRYSOSTOM (St John), a celebrated patriarch of Constantinople, and one of the most admired fathers of the Christian church, was born of a noble family at Antioch, about the year 347. He studied rhetoric under Libanius, and philosophy under Andragathus: after which he spent some time in solitude in the mountains near Antioch; but the austerities he endured having impaired his health, he returned to Antioch, where he was ordained deacon by Meletius. Flavian, Meletius's successor, raised him to the office of presbyter five years after; when he distinguished himself so greatly by his eloquence, that he obtained the surname of *Golden mouth*. Nectarius patriarch of Constantinople, dying in 397, St Chrysostom, whose fame was spread throughout the whole empire, was chosen in his room by the unanimous consent of both the clergy and the people. The emperor Arcadius confirmed this election, and caused him to leave Antioch privately, where the people were very unwilling to part with him. He was ordained bishop on the 26th of February 398; when he obtained an order from the emperor against the Eunomians and Montanists; reformed the abuses which subsisted amongst his clergy; retrenched a great part of the expences in which his predecessors had lived, in order to enable him to feed the poor and build hospitals; and preached with the utmost zeal against the pride, luxury, and

avarice of the great. But his pious liberty of speech procured him many powerful enemies. He differed with Theophilus of Alexandria, who got him deposed and banished; but he was soon recalled. After this, declaiming against the dedication of a statue erected to the empress, she banished him into Cucufus in Armenia, a most barren inhospitable place; afterwards, as they were removing him from Petyus, the soldiers treated him so roughly, that he died by the way, A.D. 407. The best edition of his works is that published at Paris in 1718, by Montfaucon.

CRYSTAL. See **CRYSTAL**.

CHUB, or **CHUBB**, in ichthyology. See **CYPRINUS**.

The resorts of this fish are easily found; for they are generally holes overshadowed by trees, and this fish will be seen floating in such almost on the surface of the water in a hot day in great numbers. They are but a poor fish for the table, and are very full of bones; but they entertain the angler very much, and are of the number of those that are easily taken. The best manner of fishing for him is thus: prepare a very strong rod of a sufficient length; fix to the hook a grasshopper; place yourself so as to be perfectly out of sight of the fish, and drop in the bait about two feet from the place where a large chub lies; if he does not see the angler he very seldom fails biting, and is immediately taken; but he is so strong a fish that he should be taken out carefully, after a great deal of playing, otherwise the tackle will be in danger; a beetle, or any large fly, will answer the purpose in the place of a grasshopper; and if none of them are to be had, the method of fishing must be altered, and the line be long enough for fishing at the bottom. In March and April this fish is to be caught with large red worms; in June and July with flies, snails, and cherries; but in August and September the proper bait is good cheese pounded in a mortar, with some saffron, and a little butter; some make a paste of cheese and Venice turpentine for the chub in winter, at which season this fish is better than at any other; the bones are less troublesome in this season, and the flesh is more firm and better tasted; the roe is also well flavoured in general. The angler must keep his bait for this fish at the bottom in cold weather, and near the top in hot, and the fish will bite eagerly.

CHUBB (Thomas), a noted polemical writer, born at East Harnham, a village near Salisbury, in 1679. He was put apprentice to a glover at Salisbury, and afterwards entered into partnership with a tallow-chandler. Being a man of strong natural parts, he employed all his leisure in reading; and though a stranger to the learned languages, became tolerably versed in geography, mathematics, and other branches of science. His favourite study was divinity; and he formed a little society for the purpose of debating upon religious subjects, about the time that the Trinitarian controversy was so warmly agitated between Clarke and Waterland. This subject, therefore, falling under the cognizance of Chubb's theological assembly, he at their request drew up and arranged his sentiments on it, in a kind of dissertation; which was afterward published under the title of *The Supremacy of the Father asserted*, &c. In this piece Mr Chubb showed great talents in reasoning; and acquired so

Church.

much reputation, that the late Sir Joseph Jekyl, master of the rolls, took him into his family to enjoy his conversation: but though he is said to have been tempted to remain with him by the offer of a genteel allowance, he did not continue with him many years; but chose to return to his friends at Salisbury. He published afterward a 4to volume of tracts, which Mr Pope informs his friend Gay, he "read through with admiration of the writer, though not always with approbation of his doctrine." He died a single man in the 68th year of his age, and left behind him 2 vols. of posthumous tracts, in which he appears to have had little or no belief in revelation. But however licentious his way of thinking may be deemed, nothing irregular or immoral has been fairly imputed to him in his life and actions.

CHUDLEIGH (Lady Mary), was born in 1656, and married to Sir George Chudleigh, baronet, by whom she had several children: her poems and essays have been much admired for delicacy of style. She died in 1710; and is said to have written several dramatic pieces, which, though not printed, are preserved in the family.

CHUPMESSAHITES, a sect among the Mahometans, who believe that Jesus Christ is God, and the true Messiah, the Redeemer of the world; but without rendering him any public or declared worship. The word in the Turkish language signifies *protector of the Christians*. Ricaut says, there are abundance of these Chupmessahites among the people of fashion in Turkey, and some even in the seraglio.

CHURCH, has different significations, according to the different subjects to which it is applied.

1. It is understood of the collective body of Christians, or all those over the face of the whole earth who profess to believe in Christ, and acknowledge him to be the Saviour of mankind. This is what the ancient writers call the *catholic* or *universal church*. Sometimes the word church is considered in a more extensive sense, and divided into several branches; as the church militant, is the assembly of the faithful on earth; the church triumphant, that of the faithful already in glory; to which the Papists add the church patient; which, according to their doctrines, is that of the faithful in purgatory.

2. Church is applied to any particular congregation of Christians, who associate together and concur in the participation of all the institutions of Jesus Christ, with their proper pastors and ministers. Thus we read of the church of Antioch, the church of Alexandria, the church of Thessalonica, and the like.

3. Church denotes a particular sect of Christians distinguished by particular doctrines and ceremonies. In this sense, we speak of the Romish church, the Greek church, the Reformed church, the church of England, &c.

The Latin or Western church, comprehends all the churches of Italy, France, Spain, Africa, the north, and all other countries whither the Romans carried their language. Great Britain, part of the Netherlands, of Germany, and of the North, have been separated from hence ever since the time of Hen. VIII.; and constitute what we call the Reformed church, and what the Romanists call the western schism.

The Greek or Eastern church, comprehends the

churches of all the countries anciently subject to the Greek or eastern empire, and through which their language was carried; that is, all the space extended from Greece to Mesopotamia and Persia, and thence into Egypt. This church has been divided from the Roman, ever since the time of the emperor Phocas.

The Gallican church, denotes the church of France, under the government and direction of their respective bishops and pastors. This church has always enjoyed certain franchises and immunities; not as grants from popes, but as derived to her from her first original, and which she has taken care never to relinquish. These liberties depend upon two maxims; the first, that the pope has no authority or right to command or order any thing either in general or in particular, in which the temporalities and civil rights of the kingdom are concerned; the second, that notwithstanding the pope's supremacy is owned in cases purely spiritual, yet in France his power is limited and regulated by the decrees and canons of ancient councils received in that realm.

4. The word church is used to signify the body of ecclesiastics, or the clergy, in contradistinction to the laity. See CLERGY.

5. Church is used for the place where a particular congregation or society of Christians assemble for the celebration of divine service. In this sense churches are variously denominated, according to the rank, degree, discipline, &c. as Metropolitan church, Patriarchal church, Cathedral church, Parochial church, Collegiate church, &c. See METROPOLIS, PATRIARCH, &c.

In ecclesiastical writers, we meet with *grand church*, for the chief church of a place; particularly in the Greek liturgy, for the church of St Sophia at Constantinople, the see of the patriarch, founded by Constantine, and consecrated under Justinian. It was at that time so magnificent, that Justinian is said to have cried out in the consecration thereof, *Ενίκησα σι, Σολομων; I have outdone thee, Solomon*. The dome, which is said to have been the first that was built, is 330 feet diameter.

The first church publicly built by the Christians, some authors maintain to be that of St Saviour at Rome, founded by Constantine; others contend, that several churches abroad, called by the name of *St Peter Vivus*, were built in honour of that apostle during his life-time.

CHURCH, with regard to architecture, Daviler defines a large oblong edifice, in form of a ship, with nave, choir, isles, chapel, belfry, &c. See each part under its proper head.

CHURCH, *Simple*, is that which has only a nave and a choir.

CHURCH *with Isles*, that which has a row of porticos, in form of vaulted galleries, with chapels in its circumference.

CHURCH *in a Greek cross*, that where the length of the traverse part is equal to that of the nave; so called because most of the Greek churches are built in this form.

CHURCH *in a Latin cross*, that whose nave is longer than the cross part, as in most of the Gothic churches.

CHURCH *in Rotundo*, that whose plan is a perfect circle, in imitation of the Pantheon.

Church.

Church.

For the form of the ancient Greek churches, when they had all their parts, it was as follows: first was a porch, or portico, called the *vaunt-nave*, *αὐτὸν*: this was adorned with columns on the outside, and on the inside surrounded with a wall; in the middle whereof was a door, through which they passed into a second portico. The first of these porticos was destined for the *energumens*, and penitents in the first stage of their repentance; the second was much longer, destined for penitents of the second class, and the catechumens, and hence called *αὐτὸν*, *ferula*, because those placed in it began to be subject to the discipline of the church. These two porticos took up about one third of the space of the church. From the second portico, they passed into the nave, *ναὸς*, which took up near another third of the church. In the middle, or at one side of the nave, was the ambo, where the deacons and priests read the gospel, and preached. The nave was destined for the reception of the people, who here assisted at prayers.

Near the entrance of this was the baptistery or font. Beyond the nave was the choir, *χοῖρος*, set with seats, and round: the first seat on the right, next the sanctuary, being for the chantor, or *choragus*.

From the choir they ascended by steps to the sanctuary, which was entered at three doors. The sanctuary had three apses in its length; a great one in the middle, under which was the altar, crowned with a baldachin, supported by four columns. Under each of the small apses, was a kind of table or cupboard, in manner of a beaufet.

Though, of the Greek churches now remaining, few have all the parts above described, most of them having been reduced to ruins or converted into mosques.

High-Church was a denomination originally given to those otherwise called *Nonjurors*, who refused to acknowledge the title of William III. to the crown of Great Britain, under a notion that James II. though excluded, was still their rightful sovereign. This appellation was given them, because they entertained high notions of the dignity and power of the church, and the extent of its prerogative and jurisdiction. And those, on the contrary, were called *low-church men*, who disapproved of the secession and obstinacy of the nonjurors, distinguished themselves by their moderation toward dissenters, and were less ardent in extending the limits of church authority. The denomination of *high-church men* is now more generally applied to all who form pompous and ambitious conceptions of the authority and jurisdiction of the church, and who would raise it to an absolute independence on all human power.

Church-Ale. See *WHITSUN-Ale*.

Church-Reeves, the same with *Church-Wardens*.

Church-Scot, or *Churches-set*, a payment or contribution, by the Latin writers frequently called *primitia seminum*; being, at first, a certain measure of wheat, paid to the priest on St Martin's day, as the first fruits of harvest. This was enjoined by the laws of king Malcolm IV. and Canute, c. 10. But after this, *Church-scot* came to signify a reserve of corn-rent paid to the secular priests, or to the religious; and sometimes was taken in so general a sense as to include poultry, or any other provision that was paid in kind to the religious. See *TITHES*.

Churchill.

CHURCH-Wardens (*ecclesie guardiani*), in the English ecclesiastical polity, are the guardians or keepers of the church, and representatives of the body of the parish. They are sometimes appointed by the minister, sometimes by the parish, sometimes by both together, as custom directs. They are taken, in favour of the church, to be, for some purposes, a kind of corporation at the common law; that is, they are enabled, by that name, to have a property in goods and chattels, and to bring actions for them, for the use and profit of the parish. Yet they may not waste the church goods, but may be removed by the parish, and then called to account by actions at common law: but there is no method of calling them to account but by first removing them; for none can legally do it but those who are put in their place. As to lands or other real property, as the church, churchyard, &c. they have no sort of interest therein; but if any damage is done thereto, the person only or vicar shall have the action. Their office also is to repair the church, and make rates and levies for that purpose: but these are recoverable only in the ecclesiastical courts. They are also joined with the overseers in the care and maintenance of the poor. They are to levy a shilling forfeiture on all such as do not repair to church on Sundays and holidays; and are empowered to keep all persons orderly while there; to which end it has been held that a church-warden may justify the pulling off a man's hat, without being guilty of either an assault or a trespass. There are also a multitude of other petty parochial powers committed to their charge by divers acts of parliament.

CHURCHILL (Sir Winston), the father of the great duke of Marlborough, was descended from an ancient and honourable family in Dorsetshire. He was born at Wotton Glanville in that county in 1610; and educated at St John's college at Oxford. He engaged in the cause of his unfortunate sovereign Cha. I. for which he suffered severely in his fortune; and having married, while young, Elizabeth, the daughter of Sir John Drake of Ashe in Devonshire, she was forced to seek a refuge in her father's house, when Mr Churchill's misfortunes left him none that he could call his own; and there most of his children were born. After the restoration, he was elected a burgess to serve in parliament for the borough of Weymouth; and, in 1669, his majesty was pleased to confer on him the honour of knighthood. The next year he was made one of the commissioners of claims in Ireland; and upon his return from thence, was constituted one of the clerks comptrollers of the green-cloth: but writing a kind of political essay upon the History of England, which gave great offence to the parliament, he was, in 1678, dismissed from his post. He was, however, soon restored to it again; and lived to see his eldest surviving son raised to the peerage, and the rest of his children in a fair way to promotion. He died in 1688.

CHURCHILL (John), Duke of Marlborough, and prince of the holy Roman empire, a most renowned general and statesman, was born at Ashe in Devonshire in 1650. He was eldest son of Sir Winston Churchill, who carried him to court while very young, and where he was particularly favoured by James duke of York, afterwards king James II. when only

Churchill. twelve years of age. In 1666, he was made an ensign of the guards during the first Dutch war; and afterwards improved himself greatly in the military art at Tangier. In 1672, Mr Churchill attended the duke of Monmouth who commanded a body of auxiliaries in the French service, and was soon after made a captain in the duke's own regiment. At the siege of Niméguen, which happened in that campaign, he distinguished himself so much that he was taken notice of by the celebrated marshal Turenne, who bestowed on him the name of the *handsome Englishman*.—In 1673, he was at the siege of Maestricht, where he gained such applause, that the king of France made him a public acknowledgment of his service; and the duke of Monmouth, who had the direction of the attack, told king Charles II. that he owed his life to Mr Churchill's bravery. In 1681, he married Sarah daughter and co-heiress (with her sister the countess of Tyrconnel) of Richard Jennings Esq; of Sandrich, in Hertfordshire. The duke of York recommended him in a very particular manner to the king; who, in 1682, created him baron of Eymouth in the county of Berwick in Scotland, and made him colonel of the third troop of guards. A little after king James's accession, he was created baron Churchill of Sandrich in the county of Hertford, and made brigadier-general of his majesty's army in the west; where, when the duke of Monmouth came to surprise the king's army, while the earl of Feverham and the majority of the officers were in their beds, he kept the enemy in play, till the king's forces had formed themselves, and thereby saved the whole army. When James showed an intention of establishing the catholic religion in Britain, lord Churchill, notwithstanding the great obligations he owed him, thought it his duty to abandon the royal cause; but even then did not leave him without acquainting him by letter with the reason of his so doing. Lord Churchill was graciously received by the prince of Orange; and was by him employed first to re-assemble the troop of guards at London, and afterwards to reduce some lately raised regiments, and to new-model the army: for which purpose he was invested with the rank and title of lieutenant-general. In 1689, he was sworn one of the privy council, and one of the gentlemen of the king's bed-chamber; and on the 9th of April following, was raised to the dignity of earl of Marlborough in the county of Wilts. He assisted at the coronation of their majesties; and was soon after made commander in chief of the English forces sent over to Holland; and here he first laid the foundation of that fame which was afterwards spread over all Europe. In 1690, he was made general of the forces sent to Ireland; where he made the strong garrisons of Cork and Kinsale prisoners of war. The year following, king William showed the good opinion he had of his conduct, by sending him to Flanders to put all things in readiness, and to draw the army together against his arrival. In 1692, he was dismissed from all his employments; and, not long after, was with some other peers committed to the tower on an accusation of high treason; which, however, was afterwards found to be a false and malicious report, the authors of which were punished. Marlborough was soon restored to favour, and in 1698 was appointed governor to the earl of Gloucester;

with this extraordinary compliment from king William, **Churchill.** "My lord, make him but what you are, and my nephew will be all I wish to see him." The same day he was again sworn one of the privy council; and in July following was declared one of the lords justices of England, for the administration of the government, in which great trust he was three times successively in the king's absence. In 1701 he was appointed general of the foot, commander in chief of the English forces, and ambassador extraordinary and plenipotentiary at the Hague. Upon the accession of queen Anne to the throne, he was elected into the order of the garter, declared captain-general of all her majesty's forces, and sent ambassador extraordinary and plenipotentiary to Holland. After several conferences about a war, he put himself at the head of the army, where all the other generals had orders to obey him. His exploits in the field have been taken notice of under the article BRITAIN, n^o 349—370: we shall therefore only take notice in this place, of the rewards and honours conferred upon him for these exploits. After his first campaign he was created marquis of Blandford and duke of Marlborough, with a pension of L. 5000 out of the post-office, to devolve for ever upon those enjoying the title of Duke of Marlborough. In 1703, he met Charles III. late emperor, going to Spain, who presented him with a sword set with diamonds. In 1704, having forced the enemy's lines at Schellenberg, he received a letter of thanks from the emperor Leopold, written with his own hand; an honour seldom done to any but sovereign princes. After the battle of Blenheim, he received congratulatory letters from most of the potentates in Europe, particularly from the States General, and from the emperor, who desired him to accept of the dignity of a prince of the empire, which with the queen's leave was conferred upon him by the title of *Prince of Mildenheim in the province of Swabia*. After the campaign was ended, he visited the court of Prussia, where he laid such schemes as suspended the disputes with the Dutch about king William's estate; which wise conduct caused the whole confederacy to acknowledge that he had done the greatest service possible to the common cause. Upon his return to England, the queen, to perpetuate his memory, granted the interest of the crown in the honour and manor of Woodstock and hundred of Wotton to him and his heirs for ever. In 1705 he made a tour to Vienna, upon an invitation of the emperor Joseph; who highly caressed him, and made him a grant of the lordship of Mildenheim. After the campaign of 1708, the speaker of the house of commons was sent to Brussels on purpose to compliment him; and on his return to England he was again complimented in the house of lords by lord chancellor Cowper. All his services, however, and all the honours conferred upon him, were not sufficient to preserve him from being disgraced. After the change of the ministry in 1710, his interest daily declined; and in 1712, on the first day of the new year, he was removed from all his places. Finding all arts used to render him obnoxious in his native country, he visited his principality of Mildenheim, and several towns in Germany; after which he returned to England, and arrived there on the day of the queen's death. After being welcomed by the nobility and foreign ministers, he

Churchill. he attended on king George I. in his public entry through London, who appointed him captain-general, colonel of the first regiment of foot-guards, one of the commissioners for the government of Chelsea hospital, and master-general of the ordnance. Some years before his death, he retired from public business. He died at Windsor-lodge in 1722, aged 73; leaving behind him a very numerous posterity, allied to the noblest and greatest families in these kingdoms. Upon his demise all parties united in doing honour or rather justice to his merit, and his corpse was interred the 9th of August following, with all the solemnity due to a person who had deserved so highly of his country, in Westminster-abbey. The noble pile near Woodstock, which bears the name of Blenheim-house, may be justly styled his monument: but without pretending to the gift of prophecy, one may venture to foretell, that his glory will long survive that structure; and that so long as our histories remain, or indeed the histories of Europe, his memory will live and be the boast of Britain, which by his labours was raised to be the first of nations, as during the age in which he lived he was deservedly esteemed the first of men. If he had foibles, as these are inseparable from human nature, they were so hidden by the glare of his virtues as to be scarcely perceived or were willingly forgotten. A certain parasite, who thought to please Lord Bolingbroke by ridiculing the avarice of the Duke, was stopped short by his Lordship; who said, "He was so very great a man, that I forget he had that vice."

Out of a variety of anecdotes and testimonies concerning this illustrious personage, collected in the new edition of the *Biographia Britannica*, the following selection may serve to illustrate more particularly his disposition and manners.

One of the first things which he did, when very young, was to purchase a box to put his money in; an indication this of the economical, not to say avaricious, temper that accompanied him through life. Dr Joseph Warton relates, that, on the evening of an important battle, the duke was heard to chide his servant for having been so extravagant as to light four candles in his tent when Prince Eugene came to confer with him. Mr Tyers, on the other hand, mentioned a circumstance which, if well founded, redounds to his grace's generosity; though in a different respect it is much to his discredit: It is, that during the rebellion 1715 he sent L. 10,000 to the earl of Mar. We consider the story as only a traditional report, which has not in itself any great degree of probability; and therefore we are by no means convinced of its truth. The late Mr Richardson junior, the painter, hath recorded a pleasing instance of the duke's calmness of disposition; for which, indeed, he was always remarkable. "The duke of Marlborough (says the writer), riding out once with Commissary Marriot, near the commissary's house in the country, it began to rain, and the duke called for his cloak; Marriot having his put on by his servant immediately. The duke's servant not bringing the cloak, he called for it again; but the man was still puzzling about the straps and buckles. At last, it raining now very hard, the duke called again, and asked him, 'what he was about that he did not bring his cloak?' 'You must stay (grumbles the fellow), if it rains cats and dogs,

N^o 80.

till I can get at it.' The duke only turned to Marriot, and said, 'I would not be of that fellow's temper.' The duke of Marlborough (adds Mr Richardson) did by nature and constitution, what Seneca judged by philosophy ought to be done. *Quid est quare ego servi mei hilarius responsum, et contumaciorem vultum, flagellis et compedibus expiem?*

Dr Swift, in one of his letters to Stella, relates the following particulars concerning the duke of Marlborough. "I was early this morning with secretary St John, and gave him a memorial to get the queen's letter for the first-fruits, who has promised to do it in a very few days. He told me 'he had been with the duke of Marlborough, who was lamenting his former wrong steps in joining with the Whigs, and said he was worn out with age, fatigue, and misfortunes.' I swear it pitted me; and I really think they will not do well in too much mortifying that man, although indeed it is his own fault. He is covetous as hell, and ambitious as the prince of it: he would fain have been general for life, and has broken all endeavours for peace, to keep his greatness, and get money. He told the queen 'he was neither covetous nor ambitious.' She said, 'if she could have conveniently turned about, she would have laughed, and could hardly forbear it in his face.' He fell in with all the abominable measures of the late ministry, because they gratified him for their own designs. Yet he has been a successful general, and I hope he will continue his command."

Various characters have been drawn of the duke of Marlborough; most of which we shall omit, as either already sufficiently known, or as not meriting particular notice. That which is given of him by Dr Swift, in his "History of the four last years of the queen," has all the malignity and meanness of a party pamphlet. It is even so foolish as to insinuate, that the duke's military accomplishments were problematical, and that he was destitute of personal courage. Mr Macpherson's character of his grace is very elaborately composed, and displays no small degree of ability and penetration; though it is not, perhaps, entirely free from prejudice. The historian considers it as a fact, that lord Churchill, at the time of the Revolution, had a design of placing his unfortunate master king James II. a prisoner in the hands of his rival the prince of Orange. But this story must be regarded as wholly unworthy of credit. It is founded upon suggestions and informations so groundless, and even ridiculous, that it cannot deserve a formal refutation. On the other hand, Mr Macpherson has done justice to the duke of Marlborough's prosecution of the war in Flanders, and hath shown that he conducted it upon the principles of sound wisdom and good policy.

There are two testimonies to the honour of the duke's memory, by two celebrated noble writers, which cannot be passed over. One is by lord Bolingbroke, in his letters on the Study and Use of History. Speaking of the consternation raised among the allies of the grand confederacy by the death of king William, and of the joy which that event gave to the French, his lordship observes, that "a short time showed how vain the fears of some and the hopes of others were. By his death, the duke of Marlborough was raised to the head of the army, and indeed of the

con-

Churchill. confederacy: where he, a new, a private man, a subject, acquired, by merit and by management, a more deciding influence than high birth, confirmed authority, and even the crown of Great Britain, had given to king William. Not only all the parts of that vast machine, the grand alliance, were kept more compact and entire, but a more rapid and vigorous motion was given to the whole: and, instead of languishing out disastrous campaigns, we saw every scene of the war full of action. All those wherein he appeared, and many of those wherein he was not then an actor, but abettor however of their action, were crowned with the most triumphant success. I take, with pleasure, this opportunity of doing justice to that great man, whose faults I knew, whose virtues I admired; and whose memory, as the greatest general, and as the greatest minister, that our country, or perhaps any other, has produced, I honour."

The other testimony to the duke's accomplishments is by the earl of Chesterfield, in his Letters to his Son. "Of all the men (says his lordship) that ever I knew in my life (and I knew him extremely well), the late duke of Marlborough possessed the graces in the highest degree, not to say engrossed them: and indeed he got the most by them; for I will venture (contrary to the custom of profound historians, who always assign deep causes for great events) to ascribe the better half of the duke of Marlborough's greatness and riches to those graces. He was eminently illiterate; wrote bad English, and spelled it still worse. He had no share of what is commonly called *parts*; that is, he had no brightness, nothing shining in his genius. He had, most undoubtedly, an excellent good plain understanding, with sound judgment. But these alone would probably have raised him but something higher than they found him; which was page to king James II.'s queen. There the graces protected and promoted him: for while he was an ensign of the guards, the duchess of Cleveland, then favourite mistress to king Charles II. struck by those very graces, gave him L. 5000; with which he immediately bought an annuity for his life of L. 500 a-year, of my grandfather Halifax; which was the foundation of his subsequent fortune. His figure was beautiful; but his manner was irresistible, by either man or woman. It was by this engaging graceful manner that he was enabled, during all his war, to connect the various and jarring powers of the grand alliance, and to carry them on to the main object of the war, notwithstanding their private and separate views, jealousies, and wrongheadednesses. Whatever court he went to (and he was often obliged to go himself to some testy and refractory ones), he as constantly prevailed, and brought them into his measures. The pensionary Heinsius, a venerable old minister, grown grey in business, and who had governed the republic of the United Provinces for more than 40 years, was absolutely governed by the duke of Marlborough, as that republic feels to this day. He was always cool; and nobody ever observed the least variation in his countenance: he could refuse more gracefully than other people could grant; and those who went away from him the most dissatisfied as to the substance of their business, were yet personally charmed with him, and in some degree comforted by his manner. With all his gentleness and gracefulness, no man

VOL. IV. Part II.

living was more conscious of his situation, nor maintained his dignity better."

A perusal of the above passage will convince us of the frivolous turn of the earl of Chesterfield's mind. His lordship, in his zeal to exalt the duke of Marlborough's external accomplishments, either forgets or depreciates the far greater talents of which he was possessed. There is an observation upon the subject in the British Biography, with which we entirely concur. "That the duke of Marlborough (says the writer) was eminently distinguished by the gracefulness of his manners, cannot be questioned: but the earl of Chesterfield appears to have attributed too much to their influence, when he ascribes—the better half of the duke of Marlborough's greatness and riches to those graces. That the uncommon gracefulness of his manners facilitated his advancement, and contributed to the success of his negotiations, may readily be admitted; but surely it must have been to much higher qualities that he owed the esteem of king William and of prince Eugene, his reputation throughout all Europe, and his many victories and conquests. It was not by a polite exterior that he obtained his laurels at Schellenberg, at Oudenarde, at Ramillies, and at Blenheim."

How much the duke of Marlborough has been celebrated by our poets, is well known by Addison's "Campaign," and Philips's "Blenheim." Mr Addison, in his Rosamond, has properly assumed another and voluntary occasion of paying a fine compliment to his grace's military exploits, and the glory by which they would be followed. Upon the duke's removal from his places, an ode was inscribed to him by Mr Somerville, animated with all the zeal of whiggish enthusiasm, and containing some passages that are truly poetical. Another ode, not much inferior in spirit, was addressed to his grace, on occasion of his embarking for Ostend in the year 1712.

The duke of Marlborough's Scots title of Baron Eymouth, being to heirs-male, died with himself; but his English title going to his daughters and their heirs-male, went into the Spencer family, who retain their own surname of Spencer.

CHURCHILL (Charles), a celebrated satirist, the son of Mr Charles Churchill curate and lecturer of St John's, Westminster, was educated at Westminster school, and received some applause for his abilities from his tutors in that famous seminary. His capacity, however, was greater than his application, so that he acquired the character of a boy that could do good if he would. As the slightest accounts of persons so noted are agreeable, it may not be amiss to observe, that having one day got an exercise to make, and from idleness or inattention having failed to bring it at the time appointed, his master thought proper to chastise him with some severity, and even reproached his stupidity: what the fear of stripes could not effect, the fear of shame soon produced, and he brought his exercise the next day, finished in such a manner, that he received the public thanks of all the masters. Still, however, his progress in the learned languages was but slow; nor is it to be wondered at, if we consider how difficult it was for a strong imagination, such as he was possessed of, to conform and walk tamely forward in the trammels of a school education: minds

5 G

like

Churchill like his are ever starting aside after new pursuits; desirous of embracing a multiplicity of amusing objects; eager to come at the end, without the painful investigation of the means. In short, for want of proper skill in these languages, he was rejected from Oxford, whither his father had sent him; and probably this might have given occasion to the frequent invectives we find in his works against that most respectable university. Upon his return from thence, he again applied to his studies in Westminster school, where, at 17 years of age, he contracted an intimacy with a lady, to whom he was married, and their mutual regard for each other continued for several years. At the usual age of going into orders, Mr Churchill was ordained by the late bishop of London, and obtained a small curacy in Wales of L. 30 a-year. Thither he carried his wife: they took a small house; and he passed through the duties of his station with assiduity and cheerfulness. Happy had it been for him had he continued there to enjoy the fruits of piety, peace, and simplicity of manners. He was beloved and esteemed by his parishioners; and though his sermons were rather above the level of his audience, they were commended and followed. But endeavouring to advance his fortune, by keeping a cyder cellar, it involved him in difficulties which obliged him to leave Wales and come to London. His father dying soon after, he stepped into the church in which he had officiated; and, in order to improve his income, which scarcely produced L. 100 a-year, he taught young ladies to read and write English at a boarding school, kept by Mrs Dennis, where he behaved with that decency and decorum which became his profession. His method of living, however, bearing no proportion to his income, he contracted several debts in the city; which being unable to pay, a jail, the terror of indigent genius, seemed ready to complete his misfortunes: but from this state of wretchedness he was relieved by the benevolence of Mr Lloyd, father to the poet of that name. Mean while, Mr Lloyd, the son, wrote a poetical epistle called the *Astor*; which being read and approved by the public, gave the author a distinguished place among the writers of his age. This induced Mr Churchill to write the *Rosciad*. It first came out without the author's name; but the justness of the remarks, and the severity of the satire, soon excited public curiosity. Though he never disowned his having written this piece, and even openly gloried in it; yet the public, unwilling to give so much merit to one alone, ascribed it to a combination of wits: nor were Messrs Lloyd, Thornton, or Colman, left unnamed upon this occasion. This misplaced praise soon induced Mr Churchill to throw off the mask, and the second edition appeared with his name at full length. As the *Rosciad* was the first of this poet's performances, so many are of opinion that it is the best. In it we find a very close and minute discussion of the particular merit of each performer; their defects pointed out with candour, and their merits praised without adulation. This poem, however, seems to be one of those few works which are injured by succeeding editions: when he became popular, his judgment began to grow drunk with applause; and we find, in the latter editions, men blamed whose

merit is incontestable, and others praised that were at that time in no degree of esteem with the judicious. His next performance was his *Apology to the Critical Reviewers*. This work is not without its peculiar merit; and as it was written against a set of critics whom the world was willing enough to blame, the public read it with their usual indulgence. In this performance he showed a particular happiness of throwing his thoughts, if we may so express it, into poetical paragraphs; so that the sentence swells to the break or conclusion, as we find in prose.

But while his writings amused the town, his actions disgusted it. He now quitted his wife, with whom he had cohabited many years; and resigning his gown and all clerical functions, commenced a complete *man of the town*, got drunk, frequented stews; and, giddy with false praise, thought his talents a sufficient atonement for all his follies. In some measure to palliate the absurdities of his conduct, he now undertook a poem called *Night*, written upon a general subject indeed, but upon false principles; namely, that whatever our follies are, we should never attempt to conceal them. This, and Mr Churchill's other poems, being shown to Dr Johnson, and his opinion being asked, he allowed them but little merit; which being told to the author, he resolved to requite this private opinion with a public one. In his next poem, therefore, of the *Ghost*, he has drawn this gentleman under the character of Pomposo; and those who disliked Mr Johnson allowed it to have merit. Mr Johnson's only reply to Churchill's abuse was, "that he thought him a shallow fellow in the beginning, and could say nothing worse of him still." The poems of *Night* and the *Ghost* had not the rapid sale the author expected; but his *Prophecy of Famine* soon made ample amends for the late paroxysm in his fame. In this piece, written in the spirit of the famous North Briton, he exerted his virulent pen against the whole Scotch nation; adopting the prejudices of the mob, and dignifying scurrility by the aid of a poetic imagination. It had a rapid and extensive sale, as prophesied by Mr Wilkes; who said, before its publication, that he was sure it must take, as it was at once personal, poetical, and political. After its appearance, it was even asserted by his admirers, that Mr Churchill was a better poet than Pope. This exaggerated adulation, as it had before corrupted his morals, began now to impair his mind: several succeeding pieces were published, which, being written without effort, are read without pleasure. His *Gotham*, *Independence*, *The Times*, seem merely to have been written by a man who desired to avail himself of the avidity of the public curiosity in his favour, and are rather aimed at the pockets than the hearts of his readers.—Mr Churchill died in 1764, of a miliary fever, with which he was seized at Boulogne in France, whither he had gone on a visit to Mr Wilkes. After his death his poems were collected and printed together in two volumes 8vo.

CHURCHING OF WOMEN AFTER CHILD-BIRTH, took its rise from the Jewish rite of purification. In the Greek church it was limited to the fortieth day after delivery; but in the western parts of Europe no certain time is observed. There is an office in the liturgy for this purpose.

CHURCH-

Churchill,
Churching.

Churchyard

Chyle.

CHURCHYARD, a piece of ground adjoining to a church, set apart for interment or burial of the dead. —In the church of Rome they are blessed or consecrated with great solemnity. If a churchyard, which has been thus consecrated, shall afterwards be polluted by any indecent action, or profaned by the burial of an infidel, an heretic, an excommunicated or unbaptized person, it must be *reconciled*; and the ceremony of the reconciliation is performed with the same solemnity as that of the blessing or consecration.

CHURCHYARD (Thomas), a poet who flourished in the reigns of Henry VIII. Edward VI. queen Mary and queen Elizabeth, was born at Shrewsbury; and inherited a fortune, which he soon exhausted in a fruitless attendance on the court, by which he only gained the favour of being retained a domestic in the family of lord Surrey; when, by his lordship's encouragement, he commenced poet. Upon his patron's death, he betook himself to arms; was in many engagements; was frequently wounded, and was twice made prisoner. He published 12 pieces, which he afterwards printed together in one volume, under the title of *Churchyard's Chips*; and also the tragedy of Thomas Mowbray duke of Norfolk. He died in 1570.

CHURLE, **CEORLE**, or **CARL**, in the Saxon times, signified a tenant at will, who held of the thanes on condition of rent and service. They were of two sorts: one rented the estate like our farmers: the other tilled and manured the demesnes, and were called ploughmen. See **CEORLE**.

CHURNING, in country affairs, the operation of making butter by agitating milk in a well known vessel called a churn. For accelerating this operation, a correspondent in the Bath Society Papers recommends a little distilled vinegar to be poured into the churn; and the butter will be produced in an hour afterwards. He acknowledges, however, that his experiments have not as yet ascertained the exact quantity of the acid which is necessary to the proper effect, nor the precise time of its being mixed with the cream. But he apprehends a table spoonful or two to a gallon of cream will be sufficient; nor would he recommend it to be applied till the cream has undergone some considerable agitation. His first trial was after the churning had been going forward half a day: whether he observed the same rule afterwards, he does not say; but all his trials proved successful, the butter being uniformly obtained in about an hour after the mixture.

CHUS, or *Chusch*, (Bible.) It is a tradition of an ancient standing, that the *Chus* of the Scriptures denotes *Ethiopia*, and *Chuschi* an *Ethiopian*: the Septuagint and Vulgate constantly translate it so; and in this they are followed by most interpreters, and by Josephus and Jerome. And yet what Bochart urges to the contrary is of no inconsiderable weight, from Ezekiel xxix. 10. in which the two opposite extremes of Egypt are designed; and therefore *Chus*, which is opposite to Syene, must be Arabia: but this is more strongly pointed out by Xenophon, by whom Ethiopia is said to be the south boundary of Cyrus's empire; and Herodotus distinguishes between the Ethiopians of Asia and Africa, conjoining the former with the Arabians.

CHYLE, in the animal economy, a milky fluid se-

creted from the aliments by means of digestion. See *Chylification*. **ANATOMY**, p. 734, 735.

CHYLIFICATION, the formation of the chyle, or the act whereby the food is changed into chyle.

The chyle has by some authors been thought to have a great resemblance in its nature and chemical analysis to milk. The subject, however, hath as yet been but little inquired into. See the article **MILK**.

CHYME, or **CHYMUS**, in the common signification of the word, denotes every kind of humour which is incrassated by concoction; under which notion it comprehends all the humours fit or unfit for preserving and nourishing the body, whether good or bad. It frequently imports the finest part of the chyle, when separated from the fæces, and contained in the lacteal and thoracic duct.

CHYMISTRY. See **CHEMISTRY**.

CHYMOLOGI, an appellation given to such naturalists as have employed their time in investigating the properties of plants from their taste and smell.

CHYMOSIS, in medicine, the act of making or preparing chyme. The word comes from *χυμος*, *succus*, of *χω*, *fundo*, "I melt." Chymosis, according to some, is the second of the concoctions made in the body; being a repeated preparation of the most impure and gross parts of the chyle, which being rejected by the lacteals, is imbibed by the meseraics, and thence carried to the liver, to be there elaborated, purified, and subtilized afresh. It is of this, according to Rogers, that the animal spirits are formed.

CHYMOSIS is also a distortion of the eye-lids, arising from an inflammation; also an inflammation of the tunica cornea in the eye.

CHYTILA, in antiquity, a liquor made of wine and oil, and sometimes used in divination.

CHYTRI, among the Athenians, a festival in honour of Bacchus and Mercury, kept on the 13th of the month Anthesterion.

CHYTRIUM (anc. geog.), a place in Ionia, in which formerly stood Clazomene; the Clazomenians, through fear of the Persians, removing from the continent to an adjacent island (Pausanias). Alexander reduced the island, by a mole or causeway, to a peninsula.

CHYTRUS (anc. geog.), an inland town of Cyprus, to the north of Citium; famous for its excellent honey.

CIANUS SINUS, (anc. geog.), a bay of Bithynia, named from the town and river Cius.

CIBALÆ, or **CIBALIS**, (anc. geog.), a town of Pannonia Inferior, on an eminence, near the lake Hülka, to the north-west of Sirmium; the country of the emperor Gratian, where he was brought up to rope-making: a place rendered famous for the surprisal and defeat of Licinius by Constantine.

CIBBER (Colley), a celebrated comedian, dramatic writer, and poet laureat to the king, was born at London in 1671. His father Caius Gabriel Cibber, was a native of Holstein, and a skilful statuary, who executed the basso relievo on the pedestal of the monument, and the two admired figures of lunatics over the piers of the gate to Bethlem Hospital in Moorfields. Colley, who derived his Christian name from the surname of his mother's family, was intended for

Cibber
"Cibdelo-
stracia.

the church, but betook himself to the stage, for which he conceived an early inclination; and he was some time before he acquired any degree of notice, or even a competent salary. His first essay in writing, was the comedy of *Love's last Shift*, acted in 1695, which met with success; as did his own performance of the character of the fop in it. From that time, as he says himself, "My muse and my spouse were so equally prolific, that the one was seldom the mother of a child, but in the same year the other made me the father of a play. I think we had a dozen of each sort between us; of both which kinds some died in their infancy, and near an equal number of each were alive when we quitted the theatre." The *Careless Husband*, acted in 1704, met with great applause, and is reckoned his best play; but none was of more importance to him than the *Non-juror*, acted in 1717, and levelled against the Jacobites. This laid the foundation of the misunderstanding between him and Mr Pope, raised him to be the hero of the *Dunciad*, and made him poet laureat in 1730. He then quitted the stage, except a few occasional performances; and died in 1757. Cibber neither succeeded in acting nor in writing tragedy; and his odes were not thought to partake of the genius or spirit he showed in his comedies.

His son *Theophilus*, also a comic actor after him, was born during a great storm in 1703; and after passing a life of extravagance, distress, and perplexity, perished in another storm in 1758, in the passage between Dublin and England. *Theophilus* married the sister of Thomas Augustin Arne, the famous musical composer; who became a celebrated tragic actress, and whose honour was sacrificed to her husband's extravagance.

CIBDELOPLACIA, in natural history; a genus of spars debased by a very large admixture of earth: they are opaque, formed of thin crusts, covering vegetables and other bodies, by way of incrustations.

Of this genus we have the following species: 1. A greyish-white one, with a rough surface. 2. A whitish-brown one: both these are friable. 3. A hard, pale-brown kind, which is the *osteocolla* of the shops. 4. The whitish-grey kind, with a smooth surface: this is the *unicornu fossile* and *ceratites* of authors. 5. The whitish-brown *coralloide* kind.

CIBDELOSTRACIA, in natural history, terrene spars, destitute of all brightness and transparency, formed into thin plates, and usually found coating over the sides of fissures, and other cavities of stones, with congeries of them of great extent, and of plain or botryoid surfaces.

Of these there are usually reckoned seven kinds: the first is the hard, brownish-white *cibdelostracium*, found in Germany: the second is the hard, whitish *cibdelostracium*, with thin crusts, and a smoother surface, found also in the Harts-forests in Germany: the third is the hard, pale-brown *cibdelostracium*, with numerous very thin crusts, found in subterranean caverns in many parts of England as well as Germany: the fourth is the white, light, and friable *cibdelostracium*, found also in Germany, but very rarely in any part of England: the fifth is the light, hard, pale-brown *cibdelostracium*, with a smooth surface, found in almost all parts of the world: the sixth is the whitish, friable, crustaceous *cibdelostracium*, with a rough-

er surface, frequent in Germany and England; and the seventh is the brownish-white friable *cibdelostracium*, with a dusty surface, found in several parts of Ireland, as well as Germany.

CIBORIA, in antiquity, the large husk of Egyptian beans, which are said to have been so large as to serve for drinking-cups; whence they had their name *ciborium*, signifying a cup, in the Egyptian language.

CIBORIUM, in ecclesiastical writers, the covering for the altar. This covering is supported by four high columns, and forms a kind of tent for the eucharist, in the Romish churches. Some authors call it *turris gestatoria* and others *pyxis*; but the *pyxis* is properly the box in which the eucharist is preserved.

CIBUS FERALIS, in antiquity, an entertainment peculiar to a funeral; for which purpose, beans, parsley, lettuce, bread, eggs, lentils, and salts were in use.

CICADA, the FROG-HOPPER or FLEA-LOCUST, in zoology, a genus of insects belonging to the order of hemiptera. The beak is inflected; the antennæ are setaceous; the four wings are membranaceous and deflected; and the feet, in most of the species, are of the jumping kind. The species are fifty-one. The larvæ of several of this genus evacuate great quantities of a frothy matter upon the branches and leaves of plants, in the midst of which they constantly reside, probably for shelter against the search of other animals, to which it would become a prey. Nature has afforded this kind of defence to insects whose naked and soft bodies might otherwise very easily be injured; perhaps also the moisture of this foam may serve to screen it from the sultry beams of the sun. On removing the foam, you discover the larva concealed underneath; but it does not long remain uncovered. It soon emits fresh foam, that hides it from the eye of observation. It is in the midst of this foamy substance the larva goes through its metamorphosis into a chrysalis and perfect insect. Other larvæ, whose bodies are not so soft, run over plants without any manner of defence, and escape from insects that might hurt them, by the nimbleness of their running, but especially of their leaping.

The chrysalids, and all the larvæ that produce them, differ little from each other, only that the former have the rudiments of wings, a kind of knob at the place where the wings will afterwards be in the perfect insect. As to other respects, the chrysalids walk, leap, and run over plants and trees; as do the larva and the frog-hopper, which they are to produce. At length they throw off their teguments of chrysalids, slip their last slough, and then the insect appears in its utmost state of perfection. The male alone is then endowed with the faculty of singing, which it exercises not with its throat, but with an organ situated under the abdomen. Behind the legs of the male are observed two valvulæ, which, raised up, discover several cavities, separated by various membranes. The middle contains a scaly triangle. Two vigorous muscles give motion to another membrane, which alternately becomes concave and convex. The air agitated by this membrane, is modified within the other cavities; and by the help of this sonorous instrument, he amorously solicits his female. By pulling the muscles of a frog-hopper lately dead, it may be made to sing. This insect begins its song early in the morning, and continues it during the heat of the noontide sun. Its lively and animated music is, to the country

zants.

country people, a presage of a fine summer, a plentiful harvest, and the sure return of spring. The cicadæ have a head almost triangular, an oblong body, their wings fastigiated or in form of a roof, and six legs with which they walk and leap pretty briskly. In the females, at the extremity of the abdomen are seen two large laminæ, between which is inclosed, as in a sheath, a spine, or lamina, somewhat serrated, which serves them for the purpose of depositing their eggs, and probably to sink them into the substance of those plants which the young larvæ are to feed upon.

CICATRICULA, among natural historians, denotes a small whitish speck in the yolk of an egg, supposed to be the first rudiments of the future chick.

CICATRIX, in surgery, a little seam or elevation of callous flesh rising on the skin, and remaining there after the healing of a wound or ulcer. It is commonly called a *scar*.

CICATRIZANTS, in pharmacy, medicines which assist nature to form a cicatrix. Such are Armenian bole, powder of tutty, &c.

Cicatrizants are otherwise called *escharotics*, *epulotics*, *incarnatives*, *agglutinants*, &c.

CICCA, in botany; a genus of the tetrandria order, belonging to the monœcia class of plants. The male calyx is tetraphyllous; there is no corolla: the female calyx triphyllous; no corolla; four styles; the capsule quadricoccous, or four berried.

CICELY, in botany, the English name of a species of chærophyllum. See CHÆROPHYLLUM

CICER, or CHICK-PEA, in botany: A genus of the decandria order, belonging to the diadelphica class of plants; and in the natural method ranking under the *Papilionaceæ*, or 32d order. The calyx is quinque-partite, as long as the corolla, with its four uppermost segments incumbent on the vexillum: the legumen is rhomboidal, turbid, and dispermous. There is but one species, which produces pease shaped like the common ones, but much smaller. They are much cultivated in Spain, where they are natives, being one of the ingredients in their olios; as also in France; but are rarely known in Britain.

END OF THE FOURTH VOLUME.

By an accident the following Explanations were omitted at their proper place, viz. at the end of Part I. of CHEMISTRY, p. 455.

Plate CXXXIII. fig. 1. shows the figure of the still recommended by Dr Black; the bottom formed in such a manner as to go into his furnace. A, the body; B, the head; C C, the tube conveying the steam into the worm; D F, the figure of the worm; E, the worm-tub.

Fig. 2. A head taller than the common, proper for rectifying ardent spirits.

Fig. 3. Another kind of still for a common furnace, having a concave bottom for receiving the flame. A, the body; B, the head.

Fig. 4. Papin's digester. See CHEMISTRY. n° 567. A, the body; B B, the cross-bars; C D, the screw; E, the lid.

Fig. 5. The outer case of Dr Black's furnace without the luting. A, the body; B, the feet; I G, the opening at top.

Fig. 6. C, the grate of the same, with four projections, having holes in them to fasten it by nails to the inside of the furnace.

Fig. 7. A crooked funnel for putting matters into a retort without touching the sides or neck.

Fig. 8. Dr Black's furnace put together in readiness for chemical operations. A, the mouth; B, the chimney; C, the door of the ash-hole. E, the registers for admitting air.

Fig. 9. A section of the same, showing its inside structure. F, the top-cover; G, the body, with part

of the grate; D, the receptacle for the ashes; C, its door; E, the registers.

Fig. 10. An iron support for a crucible.

Fig. 11. The figure of a crucible.

Plate CXXXIV. fig. 1. Dr Boerhaave's portable furnace. See CHEMISTRY, n° 600.

Fig. 2. Macquer's melting-furnace. A A, the door of the ash-pit; B, the space betwixt the top of the ash-pit and fire-place; D C, the bars; G H E F, the fire-place; I, the funnel. *Ibid.* 2d n° 605.

Fig. 3. Dr Lewis's portable furnace fitted with a still. *Ibid.* n° 601, 602.

Fig. 4. Shows the figure of retorts of different kinds. A, the body; B, the neck.

Fig. 5. A matrafs and alembic head, with a cucurbit and alembic head made of one piece. A, the body; B, the long neck of the matrafs; C, the alembic head. A, the body of the cucurbit; B, the head; C, an opening in the head for putting in the matter to be distilled; D, a glass stopple fitted to the opening just mentioned; E, the opening of the cucurbit mouth.

Fig. 6. The pelican and cucurbit, now in disuse. A, the body of the pelican; B, the head; C, an opening fitted with a stopple; D D, the arms. A, the body of the cucurbit; B, the head; C, the neck; D, the spout.

Fig. 7. A row of adopters or aludels.

Fig. 8. Dr Lewis's lamp-furnace. *Ibid.* n° 611.

E R R A T A.

Page 127. col. 1. line 10. For *flint stones*, read *flat stones*.
col. 2. l. 20. For *Sloppo*, read *Hoppo*.

In the NOTES ON CHEMISTRY.

N° 55. For *partly the pressure*, read *partly by the pressure*.

109. For *exsiccation*, read *extrication*.

140. For *the now existence*, read *nonexistence*.

147. For *coming*, read *derived*.

223. For *continuation*, read *combination*.

423. For *attestation of the density*, read *alteration of the density*.

559. For *frigidity*, read *fragility*.

904. For *phlogistic acid*, read *phosphoric acid*.

922. For *sublimes charcoal*, read *sublimes with charcoal*.

927. For *continued with*, read *combined with*.

1227. For *curious mercurius*, read *curious mercuries*.

1398. For *general vision*, read *general division*.

Page 452. col. 1. l. 20. from the top. For "HH," read "CE."

l. 23. from the top. For "E," read "D."

l. 25. For "DD," read "E."

col. 2. l. 31. from the top. For "fig. 7. and 8." read "fig. 8. and 9."

On the margin of col. 1. under note 2d 602, insert "Plate CXXXIII. fig. 5, 8, 9."

Page 454, col. 2. on the margin. For "fig. 8." read "Plate CXXXIV. fig. 8."

* * * In the System of CHEMISTRY, though an Appendix is added containing the more recent discoveries in that Science; yet as some others occurred still later, it was found necessary to insert them in the Index, where they are to be found under the articles *Nitre*, *Phosphorus*, *Sugar*, *Tartar*, and *Vegetables*.
